Investigation of Heat Transfer by Natural Convection in an Open Channel

Mahmoud S. Ahmed, Hany A. Mohamed, Mohamed A. Omara, Mohamed F. Abdeen

Abstract—Experimental study of natural convection heat transfer inside smooth and rough surfaces of vertical and inclined equilateral triangular channels of different inclination angles with a uniformly heated surface are performed. The inclination angle is changed from 15º to 90º. Smooth and rough surface of average roughness (0.02mm) are used and their effect on the heat transfer characteristics are studied. The local and average heat transfer coefficients and Nusselt number are obtained for smooth and rough channels at different heat flux values, different inclination angles and different Rayleigh numbers (Ra) 6.48 × 105 ≤ Ra ≤ 4.78 × 106. The results show that the local Nusselt number decreases with increase of axial distance from the lower end of the triangular channel to a point near the upper end of channel, and then, it slightly increases. Higher values of local Nusselt number for rough channel along the axial distance compared with the smooth channel. The average Nusselt number of rough channel is higher than that of smooth channel by about 8.1% for inclined case at θ = 45º and 10% for vertical case. The results obtained are correlated using dimensionless groups for both rough and smooth surfaces of the inclined and vertical triangular channels.

Keywords—Natural heat transfer convection, constant heat flux, open channels, heat transfer.

I. INTRODUCTION

Natural convection heat transfer has gained considerable attention because of its applications in many practical fields in the area of energy conservation, design of solar collectors, heat exchangers, nuclear engineering, cooling of electrical and electronic equipment and many others. The increasing interest in developing compact and highly efficient heat exchangers motivated researchers to study heat transfer from tubes of non-circular cross section, (elliptic, rectangular, square, etc.). Abdel-Aziz [1] studied the heat transfer by natural convection from the inside surface of a uniformly heated tube at different angles of inclination. The experiments were carried out in the range of Ra from 1.44 × 107 to 8.85 × 108, L/D from 10 to 31.4 and angle of inclination from 0º to 75º degree. The results showed that the average Num had a maximum value when the tube was vertical.

Hussein and Yasin [2] experimentally investigated heat transfer by natural convection from a uniformly heated vertical circular pipe with different entry restriction configurations by using the boundary condition of constant wall heat flux in the ranges of Ra from 1.1 × 109 to 4.7 × 109.

The apparatus was made from heated cylinder of a length 900 mm and inside diameter 30 mm. The results show that the Nusselt number values increase as the heat flux increases. Empirical correlations were proposed in the form of LogNum versus LogRam for each case investigated and a general correlation was obtained for all cases.

Sarhan et al. [3] studied the problem of natural convection to the air from the inside surface of the outer tube of the horizontal and vertical annuli with a uniformly heated outer tube and an adiabatic inner tube. The experiments covered a range of radius ratio from 0.26 to 0.71 and a range of Ra (D/L) from 1.05 × 102 to 1.2 × 104. The results obtained were correlated by dimensionless groups with the available data of vertical annuli. The results showed that the cooling by natural convection inside the annuli decreased with the increase of radius ratio.

Hosseini et al. [4] free convection in an open-ended vertical eccentric annulus with different eccentric ratios has been experimentally studied with several heat fluxes. The outer pipe was heated electrically and insulated carefully from the environment, and the inner pipe was completely filled with the ceramic wool to maintain the inner boundary insulated. The length and the radius ratio of the pipes used were 1660 mm and 0.24, respectively. The analysis of experimental results indicates that the heat transfer coefficient increases as the eccentric ratio increases up to 0.5. For ratios 0.5 – 0.7 the heat transfer coefficient remains approximately constant, and beyond that it starts to decrease and reaches a minimum at an eccentric ratio of 1.

Free convection heat transfer from the inside surface of the inclined and vertical elliptic tube of axis ratio 2:1 with a uniformly heated outer surface was experimentally studied by [5] and [6] The orientation angle (α) was changed from 0º to 90º with a step of 15º and the inclination angle (θ) was changed from 15º to 90º with steps of 15°. The experiments covered a range of Rayleigh number, (Ra) from 2.6 × 106 to 3.6 × 107 for [5] and 6.85 × 105 to 1.3 × 108 for [6]. The local and average Nusselt numbers were estimated for different orientation angles (α) and inclination angles (θ) at different Rayleigh numbers. It was found that the temperature increases with the increase of axial distance from lower end of the elliptic tube to the maximum value near the upper end. Then, the temperature gradually decreased. Also, local Nux was increased with the increase of α at the same axial distance. The mean Nusslet was increased with the increase of both α and θ.

Amr et al. [7] conducted an experimental investigation of free convection from the outer surface of an elliptic tube to air for case of constant heat flux. The local and average Nusselt number are obtained for elliptic tube at different inclination angles and different values of Rayleigh number $1.1 \times 10^7 \leq \text{Ra} \leq 8 \times 10^7$. The comparison between free convection around isothermal and constant heat flux elliptic tubes, it was made and it was found that at steady state, the heat flux tube correlates well with Rayleigh number similar to the isothermal tube. The maximum average Nusselt number is achieved by the elliptic tube with vertical major axis.

Nada [8] studied natural convection heat transfer in horizontal and vertical closed narrow enclosures with heated rectangular finned base plate. The study was experimentally investigated at a wide range of Rayleigh number (Ra) for different fin spacing and fin length values. The results show that increasing fin length increases Nusselt number (Num) and finned surface effectiveness (ε); also increasing Ra increases Num for any fin-array geometry.

Varol et al. [9] studied natural convection in a triangular enclosure with flush mounted heater on the wall. The study of natural convection heat transfer in triangular enclosure was analyzed numerically for different parameters, including the aspect ratio of triangle (AR = 1 and 0.6), Rayleigh number and both length and position of heater. The results showed that the flow and temperature fields are affected by the shape of enclosure and Rayleigh numbers play an important role on them. Both position and location of heater affect the flow circulation and heat transfer.

Experimental study of inclination angle and surface area effects for longitudinally finned cylinder on free convection heat transfer in an open enclosure was studied by [10]. This study deals with heat transfer by free convection from the outer surface of two cylinders (Triangular & Rectangular shape finned cylinder 12-fins). The experimental work was conducted with air as a heat transport medium. The cylinders were fixed at different slope angles (0º, 30º, 60º, 90º). The results show that heat transfer from the triangular finned cylinder is a maximum at a slope angle (90º) and minimum at the slope angle (0º) with the range of Ra, from $1.54 \times 10^7$ to $1.57 \times 10^8$.

Abdlmonem and Michel [11] studied the effect of surface roughness on the average heat transfer from a uniformly heated flat plate of an impinging air jet. The roughness took the shape of a circular array of protrusions of 0.5 mm base and 0.5 mm height. The results indicated an increase up to 6.0% of the average Nusselt number due to surface roughness.

Heat transfer in rough circular cylinder microfins was studied and a new analytical model was also developed by [12]. The results showed that both cross-sectional and surface areas of microfins increase by increasing roughness. Consequently, an enhancement is observed in the heat transfer rate and thermal performance of microfins. The effect of roughness is more profound in lower convective heat transfer coefficient. The rate of increase in microfin base heat flux due to roughness is higher at lower Nusselt numbers; thus, better improvement in thermal efficiency of a microfin (due to roughness) can be achieved with a natural convection regime.

Hany et al. [13] natural convection heat transfer through horizontal open ended equilateral triangular channels (smooth and rough channels) with a uniformly heated surface is experimentally studied. The effect of smooth and rough surface of average roughness ($ra = 0.02$mm) on the heat transfer characteristics are studied. The local and average heat transfer coefficients and Nusselt number were obtained for smooth and rough channels at different Rayleigh numbers from $6.45 \times 10^5$ to $4.45 \times 10^6$. The findings show that the values of temperature difference between the inside surface and ambient air increases with increase of axial distance from both ends of the channel until a maximum value at the middle of the channel. The results show higher values of local (Nux) for rough channel along the axial distance compared with the smooth channel. The average Num of rough channel is higher than Num of smooth channel by about 7%. The results obtained were correlated using dimensionless groups for both rough and smooth surfaces of the equilateral horizontal triangular channels.

In the present work natural convection heat transfer from vertical and inclined open ended equilateral triangular channel to inside air is experimentally studied. The effect of the inner surfaces roughness is taken into considerations.

II. EXPERIMENTAL SET UP AND TEST PROCEDURES

The experimental test rig is shown diagrammatically in Fig. 1. It consists of an equilateral triangular channel (test section) mounted on a frame.

![Fig. 1 Experimental setup](image-url)

The equilateral triangular channel of length 500 mm is made from copper of 1.5 mm thickness. Side length of triangle for equilateral triangular channel is 65mm. The outer surface of the triangular channel is completely covered with an electricity insulating tape as shown in Fig. 2. A nickel–chrome wire of 0.4 mm diameter is uniformly wound to form the main heater. The main heater is covered with an asbestos layer of 45 mm thickness surrounded by another nickel–chrome wire of 0.4 mm diameter was wound uniformly to form a guard heater. The guard heater is covered with a 30 mm thick
asbestos layer. Two pairs of thermocouples are installed in the asbestos layer between the main heater and the guard heater. The thermocouples of each pair were fixed on the same radial line. The guard heater is adjusted so that, at steady state, the readings of the thermocouples of each pair became practically the same. Thus, all the energy generated by the main heater should be flown inward to the triangular channel.

The inner surface temperature of the triangular channel is measured by 15 chromel-alumel thermocouples of 0.4 mm diameter soldered in slots milled along the axial and circumferential directions. The distribution of thermocouples is located for five measuring axial locations for each side surface of the triangular channel at axial distances of 50, 150, 250, 350 and 450 mm from one end of the triangular channel as shown in Fig. 3.

The calculation of heat transfer coefficient is depending on the temperature difference ($\Delta T_s$) between the inside surface temperature and the bulk temperature of the air flowing inside the triangular channel. The bulk temperature is, however, unknown. Consequently the heat transfer coefficient is calculated employing a temperature difference equal to the difference between the surface temperature $T_s$ and the temperature at the entrance to the triangular channel. All temperatures are measured by digital thermometer capable of reading ±0.1 C. The input electric power was regulated by AC power voltage transformer (variac) and is measured by a digital wattmeter with a resolution of ±0.01 W. The whole experimental set up was installed in laboratory room (closed room) with a controlled temperature environment. The input power to the main heater is controlled and changed by the AC variac for each experiment. The steady state condition for each run was achieved after 3 – 4 h approximately. The steady state condition is considered to be achieved when the temperature reading of each thermocouple was not changed by more than ±0.5 C within 20 minutes. When the steady state condition was established, the readings of all thermocouples and the input power were recorded. Two equilateral triangular channels, one has smooth surfaces and the second has rough surface of 0.02mm roughness were used for the present study.

III. ANALYSIS OF EXPERIMENTAL MEASUREMENTS

In the present work, the local heat transfer coefficient, $h_s$, between the inside surface of the triangular channel and the air inside the triangular channel is calculated by:

$$h_s = \frac{q}{\Delta T_s}$$ (1)

The temperature difference between the inside surface of the triangular channel and the bulk air is given by:

$$\Delta T_s = (T_s - T_\infty)$$ (2)

The corresponding local Nusselt number, Nu is calculated from by:

$$Nu_s = h_s \frac{D}{k}$$ (3)

where: $\Delta T_{ms} = T_{ms} - T_\infty$

The average heat transfer coefficient between the inside surface of the triangular channel and the air inside the triangular channel is calculated from:

$$h_m = \frac{q}{\Delta T_{ms}}$$ (4)

The average inner surface temperature can be estimated by:

$$T_{ms} = \frac{1}{L} \int_{x=0}^{x=L} T_{sx} \, dx$$ (5)

The corresponding average Nusselt number $Nu_m$ is calculated by:

$$Nu_m = h_m \frac{D}{k}$$ (6)

The Rayleigh number $Ra$ is calculated by:

$$Ra = Gr Pr$$ (7)

The Grashof number, Gr can be calculated by:

$$Gr = g \beta D^4 \frac{q}{k \nu^2}$$ (8)

The physical properties are evaluated at the mean film temperature as:

$$T_{mf} = \frac{(T_{ms} + T_\infty)}{2}$$ (9)

IV. UNCERTAINTY ANALYSIS

Generally, the accuracy of the experimental results depends upon the accuracy of the individual measuring instrument and the manufactured accuracy of the triangular channel. Also, the accuracy of an instrument is limited by its minimum division (its sensitivity). In the present work, the uncertainties in both the heat transfer coefficient (Nusselt number) and Rayleigh
number are estimated by using the differential approximation method. For a typical experimental, the total uncertainty in measuring the main heater input power, temperature difference ($\Delta T_s$), heat transfer rate and the triangular channel surface area were $\pm 0.23\%$, $\pm 0.6\%$, $\pm 3.1\%$ and $\pm 0.23\%$, respectively. These are combined to give a maximum error of $\pm 3.7\%$ in heat transfer coefficient (Nusselt number) and a maximum error of $\pm 5.2\%$ in Rayleigh number.

V. RESULTS AND DISCUSSION

The present experimental results for smooth and rough surfaces of vertical and inclined triangular channels with different heat flux values ($q$), different inclination angles ($\theta$) and different Rayleigh numbers ($Ra$) are discussed in this section. The results obtained in this work include the temperature distributions of channel surface temperature and local $Nu$ as well as $Nu_{m}$ vs $Ra$. The results covered ranges of $Ra$ from $6.48 \times 10^{5}$ to $4.78 \times 10^{6}$, for both smooth and rough surfaces (average roughness $r_{a}$ = 0.02mm) of the inclined ($15^\circ \leq \theta \leq 75^\circ$) and vertical ($\theta = 90^\circ$) triangular channels.

A. Temperature Difference Distribution

The results for the inside surface temperature difference ($\Delta T_s$) of the smooth triangular channel are shown in Fig. 4 for the inclined case at $\theta = 15^\circ$. Fig. 4 shows a parabolic variation of the temperature difference ($\Delta T_s$) with axial distance ($x$) for inner smooth surface. The surface temperature difference ($\Delta T_s$) gradually increase with the increase of axial distance ($x$) from the lower end of the inclined triangular channel until a maximum value near the upper end of triangular channel, then, it slightly decreases. This can be attributed to the flow of cold air entering from the lower end flowing up to the upper end due to buoyancy effect. This flow causes grow of boundary layer from the lower end until the boundary layer fills the whole triangular channel. This would, however, cause the surface temperature difference to increase. Fig. 5 shows a behavior of $\Delta T_s$-$x$ for vertical triangular channel similar to that of inclined triangular channel with $\theta = 15^\circ$ but different in $\Delta T_s$ values. Also, behaviors of stream lines of air flow inside the vertical triangular channel are different from that of the inclined triangular channels. All the air flowing inside the channel enters from the lower end and all of it exits from the upper end.

Fig. 6 shows the effect of inclination angle $\theta$ on $\Delta T_s$ at one value of heat flux ($404.6$ W/m$^2$) for triangular channel. It can be seen from Fig. 5 that the temperature difference $\Delta T_s$ decreases with increase of inclination angle, ($\theta$) at the same axial distance, ($x$) and the same heat flux, ($q$). This can be attributed to the increase of air flow and its temperature with increase of channel inclination. Thus, causes a high rate of convective heat transfer between the inside surface of the triangular channel and the air inside the triangular channel and causes reduction in $\Delta T_v$.

B. Local Nusselt Number, $Nu_s$

Fig. 7 illustrates the variation of local Nusselt number ($Nu_s$) along the axial distance of the inclined triangular channel at $\theta = 15^\circ$ and different heat fluxes. As shown from Fig. 7 the $Nu_s$ decreases with the increase of dimensionless axial distance ($x/L$) from the lower end of the inclined triangular channel until a minimum value near the upper end of channel, then, it slightly increases until the upper end of triangular channel. The boundary layer grows up causing a decrease in convective heat transfer coefficient.
Fig. 7 Variation of the local Nusselt number \( (\text{Nu}_x) \) with axial distance \( (x/L) \) for smooth triangular channel at \( \theta = 15^\circ \)

Fig. 8 shows the variation of local Nusselt number, \( \text{Nu}_x \), with dimensionless axial distance \( x/L \), for the vertical triangular channel \( (\theta = 90^\circ) \) at different heat fluxes. Fig. 7 show that \( \text{Nu}_x \) of the vertical triangular channel varies in the same way like the case of inclined channel. However in comparing the values it appears that \( \text{Nu}_x \) for vertical channel has greater values than that for the inclined case. As the temperature of the air flow increases, the air flow up due to buoyancy force. The air thus exits from the upper end. The growth of the boundary layer and the increase of air temperature with axial distance make a reduction in heat transfer coefficient.

C. Mean Nusselt Number, \( \text{Nu}_m \)

Fig. 10 shows the effect of inclination angle \( \theta \) on the average \( \text{Nu}_m \) at different heat fluxes for the smooth triangular channel. Fig. 10 shows that the average \( \text{Nu}_m \) increases with the increase of \( \theta \) at the same heat flux. The increasing of \( \text{Nu}_m \) with increase of \( \theta \) can be attributed to the increase of air flow due buoyancy force through the lower end of the triangular channel.

Fig. 9 Effect of the inclination angle \( \theta \) on local Nusselt number \( (\text{Nu}_x) \) of smooth triangular channel at \( q = 404.6 \, \text{W/m}^2 \)

Fig. 10 Effect of The inclination angle \( \theta \) on the \( (\text{Nu}_m) \) at different heat fluxes for smooth triangular channel

The variation of the average Nusselt number, \( \text{Nu}_m \), with \( \text{Ra} \) at different inclination angles (15º, 45º and 90º) is shown in Fig. 12. It shows that the value of \( \text{Nu}_m \) increases with the increase of \( \text{Ra} \) for smooth and rough channels. As shown, \( \text{Nu}_m \) increases with the increase of \( \theta \) and \( \text{Ra} \).
smooth and rough inside surfaces shows that Nu_m values for rough surface are higher than Nu_m values for smooth surface at all cases.

**D. Correlation of the Results**

The experimental results were fitted using power regression. Evaluations of the empirical correlations for both smooth and rough surface channels are as:

**Smooth and rough triangular channels at (15º ≤ θ ≤ 90º):**

- For smooth channel
  \[ Nu_m = 0.11 \cdot Ra^{0.304} \cdot (\sin \theta)^{0.013} , \ 6.48 \times 10^5 \leq Ra \leq 4.69 \times 10^6 \]  (10)

- For rough channel (r_a = 0.02mm)
  \[ Nu_m = 0.12 \cdot Ra^{0.304} \cdot (\sin \theta)^{0.013} , \ 6.49 \times 10^5 \leq Ra \leq 4.78 \times 10^6 \]  (11)

Equations (10) and (11) represent the correlation for natural convection inside smooth and rough equilateral triangular channels respectively at 6.48 × 10^5 ≤ Ra ≤ 4.78 × 10^6 and 15º ≤ θ ≤ 90º. The calculated data from (10) and (11) of the average Nusselt number (Nu_mCal) are plotted against experimental data of the average Nusselt number (Nu_mExp) in Figs. 13 (a), (b). As noted from Fig. 13, the maximum deviation between the experimental data and the correlated equations are ±9.7% for smooth channel and ±10.5% for rough channel.

**E. Comparison with the Previous Work**

1. **Inclined Channels**

   The available information about free convection from inclined elliptic tube of [6] is used for comparison. The present experimental data of inclined triangular channels (smooth and rough channels) at θ = 45º, it’s compared with the inclined elliptic tube at θ = 45º of [6] is shown in Fig. 14. It shows that the present results of free convection heat transfer inside inclined triangular channels are less than [6] for free convection heat transfer inside inclined elliptic channel (Fig. 14). Also, there is enhancement of free convection heat transfer in using triangular rough channel at different inclination angles instead of triangular smooth channel at the same working conditions.

   **Fig. 14** Comparison of the present work versus [6]

2. **Vertical Channels**

   A comparison between the present work results with [5] is shown in Fig. 15. It shows that the present results of free convection heat transfer inside vertical triangular channels are less than [5] for free convection heat transfer inside vertical elliptic channel (Fig. 15). Also, there is enhancement of free convection heat transfer in using triangular rough channel instead of triangular smooth channel at the same working conditions.

   **Fig. 15** Comparison between the present work and [5]
VI. CONCLUSIONS

Natural convection heat transfer from the inside surface of vertical and inclined equilateral triangular channels to air with a uniformly heated surface is investigated experimentally. The average roughness of rough channel was (r_a = 0.02mm). The experiments covered a range of Rayleigh number, Ra from 6.48 × 10^4 to 4.78 × 10^5. The local and average Nusselt number values are estimated for smooth and rough channels at different values of Rayleigh numbers. The following main points can be drawn from this study:

- The value of the local Nu_x in rough channel is higher than Nu_x in smooth channel.
- The local Nusselt number (Nu_x) decreases with increase of axial distance from the lower end of the triangular channel to a point near the upper end of channel, and then, it gradually increases.
- The average Nu_x increases with increasing Ra.
- There is an enhancement of heat transfer coefficient with rough surface and increase of inclination angle (θ) at the same heat flux (q), the average heat transfer coefficient (h_a) of rough channel is higher than that of smooth channel by about 8.1% in inclined case at θ = 45° and 10% in vertical case.
- Correlations of Nusselt number for natural convection inside open ended inclined and vertical equilateral triangular channels (smooth and rough channels) are obtained.
