Power Quality Improvement Using UPQC Integrated with Distributed Generation Network
B. Gopal, Pannala Krishna Murthy, G. Sreenivas

Abstract—The increasing demand of electric power is giving an emphasis on the need for the maximum utilization of renewable energy sources. On the other hand maintaining power quality to satisfaction of utility is an essential requirement. In this paper the design aspects of a Unified Power Quality Conditioner integrated with photovoltaic system in a distributed generation is presented. The proposed system consist of series inverter, shunt inverter are connected back to back on the dc side and share a common dc-link capacitor with Distributed Generation through a boost converter. The primary task of UPQC is to minimize grid voltage and load current disturbances along with reactive and harmonic power compensation. In addition to primary tasks of UPQC, other functionalities such as compensation of voltage interruption and active power transfer to the load and grid in both islanding and interconnected mode have been addressed. The simulation model is design in MATLAB/ Simulation environment and the results are in good agreement with the published work.

Keywords—Distributed Generation(DG), Interconnected mode, Islanding mode, Maximum power point tracking (MPPT), Power Quality (PQ), Unified power quality conditioner (UPQC), Photovoltaic array (PV).

I. INTRODUCTION

Electric utilities and end users of electric power are becoming increasingly concerned about meeting the growing energy demand. Seventy five percent of total global energy demand is supplied by the burning of fossil fuels. But increasing air pollution, global warming concerns, diminishing fossil fuels and their increasing cost have made it necessary to look towards renewable sources as a future energy solution. Since the past decade, there has been an enormous interest in many countries on renewable energy for power generation. The market liberalization and government’s incentives have further accelerated the renewable energy sector growth [1], [2].

Renewable energy source (RES) integrated at distribution level is termed as distributed generation. The utility is concerned due to the high penetration level of intermittent RES in distribution systems as it may pose a threat to network in terms of stability, voltage regulation and power-quality issues. Therefore, the DG systems are required to comply with strict technical and regulatory frameworks to ensure safe, reliable and efficient operation of overall network. With the advancement in power electronics and digital control technology, the DG systems can now be actively controlled to enhance the system operation with improved PQ at PCC. However, the extensive use of power electronics based equipment and non-linear loads at PCC generate harmonic currents, which may deteriorate the quality of power [3], [4].

With increasing applications of nonlinear and electronically switched devices in distribution systems and industries, power quality problems, such as harmonics, flicker, and imbalance have become serious concerns. In addition, lightning strikes on transmission lines, switching of capacitor banks, and various network faults can also cause PQ problems, such as transients, voltage sag/swell, and interruption. On the other hand, an increase of sensitive loads involving digital electronics and complex process controllers requires a pure sinusoidal supply voltage for proper load operation [5].

In order to meet PQ standard limits, it may be necessary to include some sort of compensation. Modern solutions can be found in the form of active rectification or active filtering [6]. A shunt active power filter is suitable for the suppression of negative load influence on the supply network, but if there are supply voltage imperfections, a series active power filter may be needed to provide full compensation [7].

Implementation of Custom Power Devices (CPD) like UPQC in DG or micro grid systems to improve the power quality is gaining greater importance [8]-[11]. UPQC is the integration of series and shunt active filters, connected back-to-back on the dc side, sharing a common DC capacitor [12] as shown in Fig. 1. The series component of the UPQC is responsible for mitigation of the supply side disturbances: voltage sags/swells, flicker, voltage unbalance and harmonics. It inserts voltages so as to maintain the load voltages at a desired level; balanced and distortion free. The shunt component is responsible for mitigating the current quality problems caused by the consumer: poor power factor, load harmonic currents, load unbalance etc. It injects currents in the ac system such that the source currents become balanced sinusoids and in phase with the source voltages.

In recent years, the concept of distributed generation, which permits installation of relatively small scale power generators at the medium/low voltage distribution levels of the power system, has gained widespread attention due to its technical, economical, and environmental benefits [13]. Among DG systems, photovoltaic solar systems have attracted considerable investment in several countries [14], such that significant penetration of the PV energy into distribution
networks has already taken place in Europe, through single- and three-phase systems, and more penetration is anticipated worldwide. So far, PV systems of single or double digit megawatt (MW) capacities have been connected to the power system, mainly at the sub transmission voltage levels. At the distribution voltage levels, most PV systems mainly consist of rooftop installations with capacities of a few kilowatts which are unlikely to make an impression on the distribution networks and the loads. These PV systems are not even permitted to cause a reverse power flow. This is, however, not the case for large scale PV systems which have considerably higher capacities and more sophisticated controls. Thus, in view of the increasing market for multi megawatt photovoltaic systems and in response to utility companies concerns about the impact of large-scale PV systems on the feeders/customers, investigations on the control, dynamic properties, transient performance, and interactions with the network/loads of large-scale distributed PV systems seem to be timely and of importance [15]-[18].

In this paper, the proposed configuration is new connection of a Unified Power Quality Conditioner in a distributed generation integrated photovoltaic system is presented. The proposed system consist of series inverter, shunt inverter are connected back to back on the dc side and share a common dc-link capacitor with Distributed Generation through a boost converter. Therefore power can transfer from grid to load, to compensate the voltage sag and swell, voltage interruption, harmonics and reactive power in both islanding and interconnected modes.

**II. PROPOSED UPQC-DG SYSTEM**

**A. Circuit Configuration**

The single line diagram of Distributed Generation with UPQC as shown in Fig. 2. The UPQC-DG is connected to feeder BUS and with voltage of \( u_{t1} \). The shunt part of the UPQC-DG is connected to load with a current of \( i_{l1} \). Supply voltage is denoted by \( u_{s1} \) while load voltage is \( u_{l1} \). Finally, feeder current is denoted by \( i_{f1} \) and load current is \( i_{l1} \).

Bus voltage \( u_{t1} \) is distorted and may be subjected to sag/swell. The load is a nonlinear/sensitive load which needs a pure sinusoidal voltage for proper operation while its current is non-sinusoidal and contains harmonics. If the load is a sensitive/critical load which needs a purely sinusoidal voltage and must be fully protected against distortion, sag/swell, and interruption. These types of loads primarily include production industries and critical service providers, such as medical centers, airports, or broadcasting centers where voltage interruption can result in severe economic losses or human damages.

**B. UPQC-PV Structure**

The internal structure of a UPQC-PV is shown in Fig. 3. It consists of two voltage source converters which are connected back to back through a common dc-link capacitor. In the proposed configuration, voltage source converter1 is connected in series with BUS and voltage source converter2 is connected in parallel with load at the end of Feeder.

![Fig. 1 Basic configuration of the UPQC](image)

![Fig. 2 UPQC with DG connected to the DC link](image)

![Fig. 3 Configuration of proposed UPQC with PV](image)
Each of the three VSCs in Fig. 3 is realized by a three-phase converter with a commutation reactor and high-pass output filter as shown in Fig. 5. The commutation reactor \((L_f)\) and high-pass output filter \((R_f, C_f)\) are connected to prevent the flow of switching harmonics into the power supply.

The aims of the UPQC-PV shown in Fig. 3 are:
1) To regulate the load voltage against sag/swell and disturbances in the system to protect the nonlinear/sensitive load.
2) To compensate for the reactive and harmonic components of nonlinear load current \((i_{l,1})\).
3) To compensate voltage interruption and active power transfer to the load and grid in islanding mode to protect sensitive critical load.

II. CONTROLLER DESIGNING

The controlling structure of the proposed system is composed of three following parts:
A. Shunt VSC
B. Series VSC
C. DC/DC converter

Controlling strategy is designed and applied for two interconnected and islanding modes. In interconnected mode, source and PV provide the load power together while in islanding mode, PV transfers the power to the load alone. By removing voltage interruption, system returns to interconnected mode.

A. Shunt VSC

Functions of the shunt-VSC are:
1. To compensate for the reactive component and the harmonic component of load current.
2. To compensate for interruptions and inject the active power generated by PV system to the load.

1. Shunt VSC in Interconnected Mode

Fig. 6 shows the control block diagram for the shunt voltage source converter. The measured load current \((i_{l,abc})\) is transformed into the synchronous \(dq\) reference frame by using,

\[
i_{l,dqo} = \mathbf{T}_{abc \to dqo} i_{l,abc}
\]

where the transformation matrix \(\mathbf{T}_{abc \to dqo}\) is

\[
\mathbf{T}_{abc \to dqo} = \frac{2}{3} \begin{bmatrix}
\cos(\omega t) & \cos(\omega t - 120^\circ) & \cos(\omega t + 120^\circ) \\
\sin(\omega t) & \sin(\omega t - 120^\circ) & -\sin(\omega t + 120^\circ)
\end{bmatrix}
\]

By this transform, the fundamental positive-sequence component, which is transformed into dc quantities in the \(d\) and \(q\) axes, can be easily extracted by low-pass filters (LPFs). Also, all harmonic components are transformed into ac quantities with a fundamental frequency shift

\[
i_{l,d} = \bar{i}_{l,d} + \tilde{i}_{l,d}
\]
\[
i_{l,q} = \bar{i}_{l,q} + \tilde{i}_{l,q}
\]

where \(\bar{i}_{l,d}\) and \(\tilde{i}_{l,q}\) are \(d-q\) components of load current, \(\bar{i}_{l,d}\) and \(\bar{i}_{l,q}\) are dc components, and \(\tilde{i}_{l,d}\) and \(\tilde{i}_{l,q}\) are the ac components of \(i_{l,d}\) and \(i_{l,q}\) [6]-[8].

If \(i_s\) is the feeder current and \(i_{sp}\) is the shunt voltage source converter current and knowing \(i_s = i_l - i_{sp}\), then \(d-q\) components of the shunt voltage source converter reference current are defined as follows:

\[
i_{pf,d}^{ref} = i_{l,d}
\]
\[
i_{pf,q}^{ref} = i_{l,q}
\]

Consequently, the \(d-q\) components of the feeder current are

\[
i_{x,d} = i_{l,d}
\]
\[
i_{x,q} = 0
\]
This means that there are no harmonic and reactive components in the feeder current. Switching losses cause the dc-link capacitor voltage to decrease. Other disturbances, such as the sudden variation of load, can also affect the dc link. In order to regulate the dc-link capacitor voltage, a proportional–integral (PI) controller is used as shown in Fig. 6. The input of the PI controller is the error between the actual capacitor voltage \( v_{dc} \) and its reference value \( v_{dc}^{ref} \). The output of the PI controller (i.e. delta \( i_{dc} \)) is added to the component of the shunt-ML voltage source converter reference current to form a new reference current as follows:

\[
i_{pf,d}^{ref} = i_{d} + \Delta i_{dc} \\
i_{pf,q}^{ref} = i_{q}
\]  

(9)

As shown in Fig. 6, the reference current in (9) is then transformed back into the \( abc \) reference frame. By using PWM hysteresis current control, the output compensating currents in each phase are obtained [19]-[22]. The UPQC-PV System operation with interconnected mode is shown in Fig. 7.

Fig. 7 UPQC-PV System operation with interconnected mode

\[
i_{pf,abc}^{ref} = T_{dab}i_{pf,dq0}^{ref} \quad \left( T_{dq0} = T_{abc} \right)
\]  

(10)

2. Shunt VSC in Islanding Mode

If voltage interruption occurs, the shunt inverter's operation will switch from interconnected mode to islanding mode. PV system provides required active power to stabilize load voltage. In this case, shunt inverter controls output voltage and current in order to inject to load using PI controller. Fig. 6 shows the block diagram of shunt inverter control based on the above relations to control the shunt inverter during voltage interruption and islanding mode [23]-[25]. The UPQC-PV System operation with Islanding mode is shown in Fig. 8.

B. Series VSC

Functions of the series voltage source converter are:
1) To mitigate voltage sag and swell.
2) To compensate for voltage distortions, such as Harmonics.

\[
u_{t,dq0} = T_{dq0}u_{t,abc} = u_{t1p} + u_{t1n} + u_{t10} + u_{th}
\]  

(11)

where

\[
u_{t1p} = [u_{t1p,d} \quad u_{t1p,q} \quad 0]^T \quad \text{fundamental frequency positive}
\]

\[
u_{t1n} = [u_{t1n,d} \quad u_{t1n,q} \quad 0]^T \quad \text{fundamental frequency negative}
\]

\[
u_{t10} = [0 \quad 0 \quad 0]^T \quad \text{fundamental frequency zero}
\]

\[
u_{th} = [u_{th,d} \quad u_{th,q} \quad u_{th,b}]^T \quad \text{harmonics}
\]  

(12)

\( u_{t1p}, u_{t1n} \) and \( u_{t10} \) are fundamental frequency positive, negative, and zero sequence components, respectively, and \( u_{th} \) is the harmonic component of the bus voltage. According to control objectives of the UPQC, the load voltage should be kept sinusoidal with constant amplitude even if the bus voltage is disturbed. Therefore, the expected load voltage in the synchronous dq0 reference frame \( u_{l,dq0}^{exp} \) only has one value.

\[
u_{l,dq0}^{exp} = T_{dq0}u_{l,abc}^{exp} = \begin{bmatrix} u_m \\ 0 \\ 0 \end{bmatrix}
\]  

(13)

where the load voltage in the \( abc \) reference frame \( u_{l,abc}^{exp} \) is

\[
u_{l,abc}^{exp} = \begin{bmatrix} u_m \cos(\omega t) \\ u_m \cos(\omega t - 120) \\ u_m \cos(\omega t + 120) \end{bmatrix}
\]  

(14)
The compensating reference voltage in the synchronous dqo reference frame \( u_{d_{dqo}}^{ref} \) is defined as:

\[
u_{d_{dqo}}^{ref} = u_{e_{dqo}} - u_{l_{dqo}}^{exp}
\]  \( (15) \)

This means \( u_{d_{Pd}} \) in (12) should be maintained at \( U_m \) while all other unwanted components must be eliminated. The compensating reference voltage in (15) is then transformed back into the abc reference frame. By using an improved SPWM voltage control technique (sine PWM control with minor loop feedback) [26], the output compensation voltage of the series VSC can be obtained.

C. DC/DC Converter Controlling to Obtain the Maximum Power of PV Array

PV systems are nonlinear power sources whose output power is greatly under effect of two radiation and environment temperature elements. One of the disadvantages of these systems is their low efficiency, because solar cells rarely operate at their maximum power point. So in order to increase the efficiency, as much power as possible should be extracted from the array. Temperature variation effects on cell voltage and radiation variation effects on cell current. Fig. 10 shows the equivalent circuit of PV array used in simulation [27]-[29].

In connection of the PV array to grid, a DC/DC converter is applied and is used to adapt the variable voltage of PV with the voltage of grid and extract the maximum power from the array. In respect to Fig. 11 MPPT is obtained by controlling the duty cycle of DC/DC converter switch. The widely used MPPT algorithms can be broadly classified as:

1) Perturbation and Observation (P&O) Method
   a. Conventional P&O Method
   b. Incremental Conductance Method
2) Linearity-based Methods:
   a. Short-circuit current method
   b. Open Circuit Voltage Method
3) Switching Frequency Modulation Method
4) Ripple Correlation Control Method

In this paper, algorithm of perturbation and observation (P&O) method is one of the most common methods used to achieve the maximum power point. In P&O method, a short perturbation is created in array's output voltage and then output voltage is measured. If this perturbation causes an increase in output power, then the next perturbation will be applied in this direction, and if it causes reduction, then voltage perturbation will be applied in reverse direction and this process continues till achieving the maximum power point of the array [30]. The advantage of this method is simple operation. the duty cycle of converter switch is determined by measuring voltage and array's current values in specific periods of time and applying maximum power tracking algorithm. The PV Array Current-voltage Curves & Power-voltage Curves are shown in Fig. 12.
III. SIMULATION RESULTS

The proposed UPQC-PV and its control schemes have been tested through extensive case study simulations using MATLAB. In this section, simulation results are presented, and the performance of the proposed UPQC-PV system is shown.

A. Distortion and Sag/Swell on the Bus Voltage

Let us consider that the simulink model of power system in Fig. 13 consists of three-phase three-wire 380(v) (rms, L-L), 50-Hz utilities. The BUS1 voltage contains the seventh-order harmonic with a value of 22%, voltage contains 25% sag between 0.1s<t<0.2s and 20% swell between 0.2s<t<0.3s.

The UPQC-PV is switched on at 0.02 s. The BUS voltage, the corresponding compensation voltage injected by VSC1, and finally load L voltage are shown in Fig. 8. As shown in the Fig. 8, distorted voltage of BUS is satisfactorily compensated for across the loads L with very good dynamic response. The nonlinear load current, its corresponding compensation current injected by VSC2, compensated Feeder1 current, and, finally, the dc-link capacitor voltage are shown in Fig. 14. The distorted nonlinear load current is compensated very well, and the total harmonic distortion (THD) of the feeder current is reduced from 28.5% to less than 5%. Also, the dc voltage regulation loop has functioned properly under all disturbances, such as sag/swell in both feeders.

B. Upstream Fault on Feeder

When a fault occurs in Feeder (in any form of L-G, L-L-G, and L-L-L-G faults), the voltage across the nonlinear sensitive/critical load L is involved in sag/swell or interruption. This voltage imperfection can be compensated for by PV source through VSC2.

In this case, the power required by load L is supplied through PV system and VSC2. This implies that the power semiconductor switches of VS12 and VSC2 must be rated such that total power transfer is possible. This may increase the cost of the device, but the benefit that may be obtained can offset the expense. In the proposed configuration, the nonlinear sensitive/critical load on Feeder is fully protected against distortion, sag/swell, and interruption. Furthermore, the regulated voltage across the sensitive load on Feeder1 can supply several customers who are also protected against distortion, sag/swell, and momentary interruption. Therefore,
the cost of the UPQC-PV must be balanced against the cost of interruption, based on reliability indices, such as the customer average interruption duration index (CAIDI) and customer average interruption frequency index (CAIFI). It is expected that the UPQC-PV cost can be recovered in a few years by charging higher tariffs for the protected lines.

The performance of the UPQC-PV under a fault condition on Feeder is tested by applying a three-phase fault to ground on Feeder between 0.6s<t<0.7s. Simulation results are shown in Fig. 15.

Fig. 15 Simulation result for upstream fault on feeder: Bus voltage, compensating voltage, load voltage

C. Load Change

To evaluate the system behavior during a load change, the nonlinear load L is doubled by reducing its resistance to half at t= 0.5s. The system response is shown in Fig. 16. It can be seen that as load L changes and the load voltage is remain undisturbed, the dc bus voltage is regulated, and the nonlinear load current is compensated.

Fig. 16 Simulation results for load change: nonlinear load current, Feeder current, load voltage, and dc-link capacitor voltage

IV. CONCLUSION

The new configuration is named unified power-quality conditioner with Photo Voltaic System (UPQC-PV). Compared to a conventional UPQC, the proposed topology is capable of fully protecting critical and sensitive loads against distortions, sags/swell, and interruption in both islanding and interconnected modes. The performance of the UPQC-PV is evaluated under various disturbance conditions and it offers the following advantages:

1) To regulate the load voltage against sag/swell and disturbances in the system to protect the nonlinear/sensitive load.
2) To compensate for the reactive and harmonic components of nonlinear load current.
3) To compensate voltage interruption and active power transfer to the load and grid in islanding mode to protect sensitive critical load.
4) Depending upon the ratings, the combined system can reduce the cost up to one fifth of the separate system. Capacity enhancement has been achieved using multi-level or multi-module and central control mode, however, the flexibility of UPQC to increase its capacity in future and to cope up with the increase load demand in medium voltage distribution system.
