Estimation of the Temperatures in an Asynchronous Machine Using Extended Kalman Filter

Yi Huang, Clemens Guehmann

Abstract—In order to monitor the thermal behavior of an asynchronous machine with squirrel cage rotor, a 9\textsuperscript{th}-order extended Kalman filter (EKF) algorithm is implemented to estimate the temperatures of the stator windings, the rotor cage and the stator core. The state-space equations of EKF are established based on the electrical, mechanical and the simplified thermal models of an asynchronous machine. The asynchronous machine with simplified thermal model in Dymola is compiled as DymolaBlock, a physical model in MATLAB/Simulink. The coolant air temperature, three-phase voltages and currents are exported from the physical model and are processed by EKF estimator as inputs. Compared to the temperatures exported from the physical model of the machine, three parts of temperatures can be estimated quite accurately by the EKF estimator. The online EKF estimator is independent from the machine control algorithm and can work under any speed and load condition if the stator current is nonzero current system.

Keywords—Asynchronous machine, extended Kalman filter, resistance, simulation, temperature estimation, thermal model.

I. INTRODUCTION

Wireless sensor network has so many important applications such as the monitoring of the environment, the industry and the tracking of things. We focus on the algorithm implementation in one host sensor node and the input signals acquired from distributed sensor nodes. As a sensor node is low-cost, low-power, weak calculation and small in memory size, the algorithm should be simple and efficient so that it can be implemented in a sensor node. The thermal behavior monitoring system of an asynchronous machine is examined for the further implementation on a sensor node.

Asynchronous machines are widely used due to their low cost, robustness and low maintenance requirements. The thermal behavior of an asynchronous machine largely determines the maximum lifetime, the ability of over-load and also the accuracy in high-performance controller [1]. Thermal stress and exceeding of the temperature protection class may be the reason for insulation deterioration as well as rotor faults [2]. So the temperature monitoring of the stator winding, rotor cage and stator core can be used for thermal fault detection and predictive monitoring. It can help the machine to extend the life span and contribute much to the high performance of the machine [2].

The most common method is the construction of a temperature measurement system using mounted sensors. Sensors can be fixed on the surface of the stator core and embedded inside the stator winding. However, it is difficult to acquire signals from the rotor while in operation. Local temperature measurement, hot-spot measurement and bulk measurement are described in [3]. Wireless sensor networks can be used to acquire the rotor temperature, but the high cost and the instability would be an obstacle for the production [4], [5]. Two other types of indirect approaches are the temperature calculation based on the thermal model only, and the method based on the estimation of resistive parameters. Thermal analysis based on lumped-parameter thermal network, finite-element analysis, and computational fluid dynamics are considered [6]. The design of a state-of-the-art rotor temperature monitoring system for contact measurement was proposed [7]. Based on the stator windings resistance variation with temperature, a sensorless internal temperature monitoring method for induction motor is introduced [1]. J.K.Al-Tayie [8] proposed a method to estimate the rotor and stator temperatures using the extended Kalman filter. However, only the temperatures of rotor cage and stator winding can be estimated. Moreover, it must be assumed that there is no rise in the coolant air temperature.

The thermal modeling of the machine is a complex multi-disciplinary problem, and it must also evaluate the main internal losses of the machine [9]. The most frequent estimation techniques rely on a calculation of impedance in steady state [10], [11] or on an extended Kalman filter. The estimation of the stator resistance \( R_s \) and rotor resistance \( R_r \) have presented in [8] and [12], and none of them can estimate the resistances simultaneously.

Combining the electrical and mechanical model with a simplified thermal model, an online approach to estimate the temperatures of stator windings, rotor cage and stator core is proposed. The extended Kalman filter can process the three-phase voltages, currents and the coolant air temperature. This paper defines the state-space equations of the system and how to implement the temperature monitoring system using the extended Kalman filter step by step to estimate the three temperatures of the machine directly. The state-space of the system is presented in Section II. Section III illustrates the implementation of EKF and the tuning of the covariance matrix. In Section IV, the EKF estimator is performed in MATLAB/Simulink and the simulation results are discussed. Finally, the conclusions are given in the last section.

II. THE MODEL OF THE SYSTEM

EKF algorithm requires a state-space model of the whole system which consists of the electrical and mechanical models...
of the asynchronous machine in the a reference frame, and also
the simplified thermal model of the machine.

A. The Model of the Asynchronous Machines

The twin-axis reference frame is used to build the electrical model of the three-phase asynchronous machine. The voltage equations in arbitrary reference frame are often written in the form below:

\[ v_{qs} = R_s i_{qs} + \lambda_d + \lambda'_d \]  (1)
\[ v_{ds} = R_s i_{ds} - \omega \lambda_s + \lambda'_s \]  (2)
\[ v_{qr} = R_r i_{qr} + (\omega - \omega_r) \lambda_{dr} + \lambda'_r \]  (3)
\[ v_{dr} = R_r i_{dr} - (\omega - \omega_r) \lambda_{qr} + \lambda'_r \]  (4)
\[ \lambda_d = L_s i_{qs} + L_m (i_{qs} + i_{qr}) \]  (5)
\[ \lambda_{ds} = L_s i_{ds} + L_m (i_{ds} + i_{dr}) \]  (6)
\[ \lambda_{qr} = L_r i_{qr} + L_m (i_{qs} + i_{qdr}) \]  (7)
\[ \lambda_{dr} = L_r i_{dr} + L_m (i_{ds} + i_{qdr}) \]  (8)

where \( v_{qs}, v_{ds}, v_{qr}, v_{dr} \) are stator voltages, \( i_{qs}, i_{ds} \) are d-q stator currents, \( i_{qr}, i_{dr} \) are d-q rotor currents. \( R_s, R_r \) are stator and rotor resistance. \( \omega \) is the reference frame speed and \( \omega_r \) is the rotor electric speed. \( \lambda_d, \lambda_s, \lambda_{qr} \) and \( \lambda_{dr} \) are stator and rotor flux linkages in d-q axis. \( L_s, L_r \) are stator and rotor inductances and \( L_m \) is mutual inductance.

In order to reduce the number of variables, stator current \( i_{ds} \) and \( i_{qs} \), rotor current \( i_{dr} \) and \( i_{qr} \) in twin-axis stator reference frame is selected. The value of \( \omega \) is zero, and \( \sigma = L_s \omega - L_m \). The final equations can be rearranged into state-space format:

\[ \sigma i'_{ds} = -R_s L_r i_{ds} + L_m^2 \omega i_{qs} + R_e L_m i_{dr} + L_r L_m \omega i_{qr} + L_r v_{ds} \]  (9)
\[ \sigma i'_{qs} = -R_s L_r i_{qs} - L_m^2 \omega i_{ds} + R_e L_m i_{qdr} + L_r L_m \omega i_{qdr} + v_{ds} \]  (10)
\[ \sigma i'_{dr} = -R_s L_r i_{dr} - L_m L_m \omega i_{qs} - R_e L_s i_{dr} - L_s \omega i_{qr} - L_m v_{ds} \]  (11)
\[ \sigma i'_{qdr} = L_s L_m i_{qdr} + R_s L_m i_{qs} + L_s L_r \omega i_{dr} - R_e L_s i_{qdr} - L_m v_{ds} \]  (12)

The general mechanical model of the system comes from the torque balance equation which can be expressed as:

\[ T_e = F_f \omega_r + J \omega''_r + T_i \]  (13)

where \( T_e \) is the electromagnetic torque and \( T_i \) is the load torque. \( F_f \) is the friction constant and \( J \) is total inertia. Total electromagnetic torque of the asynchronous machine \( T_e \) can be expressed by the stator and rotor current component in twin-axis reference frame:

\[ T_e = p_n L_m (i_{qs} i_{dr} - i_{ds} i_{qr}) \]  (14)

where \( p_n \) is the number of pair pole. From (13), (14), the state-space of the rotor speed is shown below:

\[ \omega'_r = \frac{p_n L_m}{J} (i_{qs} i_{dr} - i_{ds} i_{qr}) - \frac{F_f \omega_r}{J} - \frac{T_i}{J} \]  (15)

B. The Thermal Model of the Asynchronous Machines

The thermal model of the machine is based on the thermal equivalent network established in [13]. The heat of the machine is generated from the power losses, which consists of the losses of stator winding, losses of the stator core, losses of the rotor cage, losses of the rotor core, friction losses and stray load losses [14]. There is no core in the squirrel cage rotor, so the losses of rotor core is taken as zero. In order to simplify the thermal model, the friction losses and the stray load losses are dissipated to the environment and not contribute to the thermal transfer. The simplified thermal model equations in [13] can be written as following equations:

\[ T'_{sw} = -\frac{R_{sw} T_{sw}}{C_{sw}} + \frac{R_{sw} T_{sc}}{C_{sw}} + \frac{P_{sw}}{C_{sw}} \]  (16)
\[ T'_{rc} = -\frac{R_{rc} T_{rc}}{C_{rc}} + \frac{R_{rc} T_{sc}}{C_{rc}} + \frac{P_{rc}}{C_{rc}} \]  (17)
\[ T'_{sc} = -\frac{R_{sc} T_{sw}}{C_{sc}} + \frac{R_{sc} T_{rc}}{C_{sc}} + \frac{R_{sc} T_{sc}}{C_{sc}} + \frac{(R_{sw} + R_{rc} + R_{sc}) T_{sc}}{C_{sc}} + \frac{P_{sc}}{C_{sc}} \]  (18)

where \( T_{sw}, T_{rc}, T_{sc} \) and \( T_r \) are temperatures above ambient of stator winding, rotor cage, stator core and coolant air respectively. \( R_{sw}, R_{rc}, R_{sc} \) are thermal resistances, \( C_{sw}, C_{rc} \) and \( C_{sc} \) are thermal capacitances. \( P_{sw}, P_{rc} \) and \( P_{sc} \) are the losses respect to stator winding, rotor cage and stator core.

In the simplified thermal model, \( P_{sw}, P_{rc} \) are ohmic losses, and \( P_{sc} \) is the frequency-dependent iron losses, \( R_s, R_r \) are DC resistance, in ohms, between any two line terminals, \( \omega_m \) is the mechanical speed of the rotor in rad/s, \( \kappa_{iron} \) is the iron loss constant. The losses can be represented as:

\[ P_{sw} = \frac{3}{2} R_s (i_{qs}^2 + i_{ds}^2) \]  (19)
\[ P_{rc} = \frac{3}{2} R_r (i_{qr}^2 + i_{dr}^2) \]  (20)
\[ P_{sc} = \kappa_{iron} \omega_m^2 \]  (21)

C. The Combined Model of the System

In order to combine the model of the asynchronous machines and the thermal model into a series of integrated state-space equations, the temperature dependent characteristics of the resistance is used. Both \( R_s \) and \( R_r \) can be replaced by the following equations:

\[ R_s = R_s_{Ref}(1 + \alpha_s T_{sw}) \]  (22)
\[ R_r = R_r_{Ref}(1 + \alpha_r T_{rc}) \]  (23)

where \( R_s_{Ref}, R_r_{Ref} \) are the resistances in the reference temperature, \( \alpha_s, \alpha_r \) are temperature coefficients of stator winding (copper) and rotor cage (aluminum).

From (9)-(12), (15), (16)-(18), the final state space system can be acquired by substituting \( P_{sw}, P_{rc}, P_{sc} \) expressed in (19)-(20) into (16)-(18), and substituting \( R_s, R_r \) in (22), (23) into (9)-(12), (16)-(18). Summarizing the previous equations,
the system can be rewritten as a 9th-order nonlinear continuous time-variant system in the state space model form:

\[
x'(t) = A(x(t))x(t) + B(t)u(t)
\]

(24)

\[
z(t) = Cx(t) + D(t)u(t)
\]

(25)

where:

\[
x = [i_{ds}, i_{qs}, i_{dr}, i_{qr}, \omega_r, T_1, T_{sw}, T_{rc}, T_{sc}]^T
\]

(26)

\[
z = [v_{ds}, v_{qs}, T_c]^T
\]

(27)

\[
u = [\dot{v}_{ds}, \dot{v}_{qs}]^T
\]

(28)

\[
A = \begin{bmatrix}
L_p & L_p & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
L_p & L_p & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]

(29)

\[
B(t) = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]

(30)

\[
\delta = L_pL_r - L^2_m
\]

(31)

\[
a(t) = (R_s(1 + \alpha_sT_{sw}(t)))
\]

(32)

\[
b(t) = (R_r(1 + \alpha_rT_{rc}(t)))
\]

(33)

In the state equations, \(x(t)\) is the state vector, \(u(t)\) is the control vector, the system matrix \(A(x(t))\) defined in (48) is variable with time, \(B(t)\) is the input matrix which is constant. In the measurement equations, \(C(t)\) is the output matrix, \(D(t)\) is the feedthrough matrix which is zero here. The load torque \(T\) is considered constant parameter due to the slow variation with time.

### III. THE IMPLEMENTATION OF EXTENDED KALMAN FILTER ALGORITHM

The extended kalman filter is a nonlinear version of the Kalman filter which linearizes about an estimation of the current mean and covariance. In general, both the process noise and the measurement noise should be taken into account in the nonlinear system model and measurement model.

\[
x_k = f(x_{k-1}, u_{k-1}) + w_{k-1}
\]

(34)

\[
z_k = h(x_k) + v_k
\]

(35)

It is necessary to assume that the process \(w_k\) and the measurement noise \(v_k\) are random white Gaussian noise with zero mean and their variance can be described by covariance matrix \(Q\) and \(R\) respectively. They can be defined as

\[
E[w(i)w^T(j)] = Q\delta(i,j)
\]

(36)

\[
E[v(i)v^T(j)] = R\delta(i,j)
\]

(37)

\[
E[W(i)c^T(j)] = 0
\]

(38)

\(\delta(i,j)\) is a Dirac Delta function variation

\[
\delta(i,j) = \begin{cases}
1 & i = j \\
0 & i \neq j
\end{cases}
\]

(39)

where \(Q\) is a 9x9 positive semi-defined matrix and \(R\) is 2x2 positive semi-defined matrix. Both of them are constant matrix. The state space of the system is nonlinear.

#### A. Initialization of the State Vector and Covariance Matrix

As the discrete EKF is a recursive algorithm starting from sampling time \(t = 0\), the starting values of the state vector is

\[
\hat{x}(0) = E[x(0)]
\]

(40)

where the symbol \(\hat{\cdot}\) indicates estimated value of a state vector. And a 9x9 error covariance matrix is a diagonal matrix as below:

\[
P(0) = Var[x(0)]
\]

(41)

#### B. The Prediction Stage of EKF

The prediction stage equations of EKF are shown in (42) and (43). Equation (42) is used for updating the state vector from previous sampling time \(k-1\) to current time \(k\). Equation (43) is state of updating error covariance matrix.

\[
\hat{x}_k^- = f(\hat{x}_{k-1}, u_{k-1}, 0)
\]

(42)

\[
\hat{P}_k^- = F_k\hat{P}_{k-1}F_k^T + Q
\]

(43)

where \(F_k\) is the process Jacobians at step \(k\)

\[
F_k = \frac{\partial f}{\partial x}|_{x=\hat{x}_k^-}
\]

(44)

1) The Discretization of the Model: The model above is a continuous time system which can not be processed by computer. Euler’s approximation is used to discrete the model, so that the sampled data can be used in the EKF algorithm. According to the definition of derivative, (24) can be rewritten as:

\[
x(k) - x(k-1) = A_d x(k-1) + B_d u(k-1)
\]

(45)

By simplifying the equation above, the new equation can be expressed as:

\[
x(k) = (1 + \tau A_d) x(k-1) + \tau B_d u(k-1)
\]

(46)

As \(A\) and \(B\) are the matrix, the discrete model is

\[
x(k) = A_d x(k-1) + B_d u(k-1)
\]

(47)

where \(A_d = E + \tau A\) and \(B_d = \tau B\), \(E\) is 9x9 unit matrix, \(C_d\) is equal to \(C\), \(\tau\) is the sampling time.
2) The Linearization of the Model: The linearization of the non-linear model plays crucial role in the implementation of EKF. The linearization is based on the assumption, that the state variables in (26) are constant in one step of the computation. The linearized state equation can be rewritten in a new form:

$$\frac{\partial f}{\partial x} = \frac{\partial A_d(k)}{\partial x}(x(k-1) + B_d(k)u(k-1))$$ (49)

And the output equation is below:

$$\frac{\partial h}{\partial x} = \frac{\partial h(x(k-1))}{\partial x}$$ (50)

The Jacobian matrix $F_k$ is defined in (55), where the coefficients are below:

$$f_{15} = \frac{L_m^2i_{q2}(k) + L_tL_m^2i_{qr}(k)^\tau}{\delta }, f_{17} = -\frac{R_t\alpha_sL_t}{\delta } + \frac{R_t\alpha_sL_ti_{ds}(k)^\tau}{\delta }$$

$$f_{18} = \frac{R_t\alpha_sL_t}{\delta } + \frac{R_t\alpha_sL_ti_{ds}(k)^\tau}{\delta }, f_{25} = -\frac{L_tL_mi_{ds}(k) + L_tL_di_{dr}(k)^\tau}{\delta }$$

$$f_{27} = -\frac{R_t\alpha_sL_t}{\delta } + \frac{R_t\alpha_sL_ti_{qs}(k)^\tau}{\delta }, f_{28} = \frac{R_t\alpha_sL_ti_{qr}(k)^\tau}{\delta }, f_{35} = \frac{L_tL_mi_{qs}(k) + L_tL_di_{qr}(k)^\tau}{\delta }, f_{37} = -\frac{R_t\alpha_sL_tL_mi_{ds}(k)^\tau}{\delta }$$

$$f_{38} = -\frac{R_t\alpha_sL_t}{\delta } + \frac{R_t\alpha_sL_ti_{ds}(k)^\tau}{\delta }, f_{45} = \frac{L_tL_mi_{ds}(k) + L_tL_di_{dr}(k)^\tau}{\delta }$$

$$f_{47} = -\frac{R_t\alpha_sL_t}{\delta } + \frac{R_t\alpha_sL_ti_{qs}(k)^\tau}{\delta }, f_{48} = \frac{R_t\alpha_sL_ti_{qr}(k)^\tau}{\delta }, f_{77} = 1 + \frac{3(R_t\alpha_s(i_{ds}(k)^2 + i_{qr}(k)^2) - R_{sw})}{2C_{sw}}$$

$$f_{88} = 1 + \frac{3(R_t\alpha_s(i_{dr}(k)^2 + i_{qr}(k)^2) - R_{rc})}{2C_{rc}}$$

$$f_{99} = 1 - \frac{(R_{sw} + R_{sc} + R_{rc})}{C_{ec}}$$

C. The Correction Stage of EKF

$$K_k = P_k^{-1}K_k^T = (H_jP_k^{-1}H_j^T + R)^{-1}$$ (51)

$$\hat{x}_k = \hat{x}_k + K_k(z_k - h(\hat{x}_k, 0))$$ (52)

$$P_{k+1} = (I - K_kH_j)P_k$$ (53)

where $K_k$ is the measurement Jacobian at step $k$

$$H_k = \frac{\partial h}{\partial x}|_{x = \hat{x}_k}$$ (54)

IV. SIMULATION MODELS AND EXPERIMENT RESULTS

A. The Combined Simulation Models

The model of a squirrel cage asynchronous machine with losses couples with the simplified thermal model using Dymola. The squirrel cage asynchronous machine with losses is explained in [14]-[16]. The model can simulate the transient electrical and magnetic behavior as well as six parts of the machine losses. By connecting an internal thermal port of the machine to the thermal port of the simplified thermal model, all the losses can be passed to the thermal circuit. With the complete model, the temperatures of stator winding, rotor cage and the stator core can be calculated. The simplified thermal model is shown in Fig. 1, and both the simulation model and the experiment are explained in [13].

All parameters of the asynchronous machine were identified at a test bench. The complete model is shown in Fig. 2.

With the help of the Dymola-Simulink interface, the complete model in Dymola can also run in a Simulink environment [17]. Meanwhile EKF algorithm is implemented as a S-Function in Matlab/Simulink, and connected with the complete physical model. In the complete model, the three-phase stator currents are the measurements, the three-phase voltages and the coolant air temperature are the control vector. They can be exported from DymolaBlock as the input of the EKF. The estimated temperature from EKF can be compared with the temperature calculated by the thermal model. The online EKF estimator in Simulink is shown in Fig. 3.

B. The Simulation Results by EKF Estimator

The parameters of the asynchronous machine and the parameters of the thermal model are listed in Tables III-V respectively. The implemented EKF algorithm is independent from the control strategy and the running conditions of the machine. The temperatures of stator winding, rotor cage and stator core can be estimated in any operating condition. Full-load test S1 and intermittent-load test S6 have performed in Simulink and the sampling time is 500 μs. The initial error covariance matrix, process noise covariance matrix and measurement covariance matrix are obtained by trial and error method:

$$P(0) = \text{diag} [5 5 5 5 5 0 0 0]$$
Apart from the deviation for every point, the normalized root-mean-square error (NRMSR) \( e_{NRMS} \) defined in (56) is used to evaluate the accuracy of the estimator.

\[
e_{NRMS} = \sqrt{\frac{1}{N} \sum_{i=0}^{N} \left( y_{mea}(i) - y_{est}(i) \right)^2}
\]

(56)

The estimated temperatures follow the simulated reference temperatures quite well. The maximum error and the NRMSE value for each region under S1 condition are summarized in Table I.

Another experiment is called S6 which is an intermittent load with six minutes no-load followed by four minutes full-load. The sampling time is also 500 \( \mu s \). The results of the temperatures match the simulated reference temperatures very well. Fig. 5 shows the comparison between the temperature simulated and the temperature estimate by EKF under an...
V. CONCLUSION

This paper proposed an on-line method to estimate the temperatures of stator winding, rotor cage and stator core of an asynchronous machine using an extended Kalman filter. By combining the model of the asynchronous machine in twin-axis stator reference frame and the simplified thermal model, the state-space equations have been defined and implemented as a 9th-order extended Kalman filter. The complete temperature simulation model based on [13] is modeled in Dymola and runs well compared to the results in [13]. The coolant air temperature, three-phase currents and voltages are exported from the asynchronous machine model in Dymola which are the inputs of EKF. Both the Dymola model and EKF algorithm complied in an S-Function can be simulated in MATLAB/SIMULINK. The estimated temperatures follow the simulated reference temperatures very

intermittent load S6. The maximum error and the NRMSE value for each region under S6 condition are summarized in Table II.

well under both S1 and S6 conditions. The advantages of the algorithm are as follows:

- The estimated temperatures can be obtained by acquiring the three phase stator voltage, current and the coolant air temperature. The rotor speed and the torque can also be estimated simultaneously.
- The estimator is independent from the operation conditions. That means no matter what the rotor speed is, and what the mechanical load is, as long as there are currents through the stator winding, the temperature can be estimated correctly.
