Sensorless Control of Induction Motor: Design and Stability Analysis

Nadia Bensiali, Erik Etien, Amar Omeiri and Gerard Champenois

Abstract—Adaptive observers used in sensorless control of induction motors suffer from instability especially in regenerating mode. In this paper, an optimal feed back gain design is proposed, it can reduce the instability region in the torque speed plane.

Keywords—Induction motor drive, adaptive observer, regenerating mode, stabilizing design.

I. INTRODUCTION

During the last decade, there has been a considerable interest in studying stability of adaptive observers used in sensorless control of induction motors. This is mainly due to their economical benefit and fragility of mechanical sensors and also the difficulty of installing this type of sensor in many applications. These systems suffer from instability problems and sensitivity to parameter mismatch at low speed operation. The sensorless systems require estimation of internal state variables of the machine such as speed and rotor flux from input variables like stator voltage and stator current [1] [3].

Many works were led in order to eliminate or to reduce unstable regions. They acts on:

- speed adaptation law [6];
- feedback gain [4], [7];
- speed adaptation law and feedback gain simultaneously [2].

In this paper, first, stability of induction motor alone is done and second the design of a feed back gain that minimizes the instability regions in the torque-speed plane to a straight line corresponding to DC excitation is described.

II. CONTROLLER DESIGN

The four parameter induction motor model using complex notations is described in the synchronous rotating reference frame by the following equations:

\[
\begin{align*}
\frac{d}{dt} \psi_{rd} &= -\frac{1}{\tau_r} \delta \psi_{rd} + \omega_{st} \psi_{rd} + R_R i_s, \\
\frac{d}{dt} \psi_{sd} &= -\frac{1}{\tau_r} \delta \psi_{sd} + \omega_{st} \psi_{sd} + R_R i_s + \frac{1}{\tau_s} u_s, \\
\frac{d}{dt} \delta \omega &= \frac{p^2}{J} \delta \omega.
\end{align*}
\]

With: \( \tau_r = \frac{L_s}{R_s + R_R} \) and \( \tau_s = \frac{L_M}{R_s + R_R} \).

\( i_s = i_{sd} + j i_{sq} \) stator current space vector

\( \psi_{rs} = \psi_{rsd} + j \psi_{rse} \) Rotor flux space vector

\( \psi_{ref} \) Rotor flux reference

\( \omega_{st} \) slip frequency

\( \omega \) electrical rotor speed

\( R_s, R_R \) Stator and Rotor resistance

\( L_M, L_s \) Magnetizing and Leakage inductance

\( \psi_{rd} \) rotor flux reference

\( \omega = \omega_{r} + s \omega_{so} \) electrical rotor speed

\( s \) slip

\( \omega_{so} \) rotor speed

\( \tau \) rotor time constant

\( L \) inductance

\( R \) resistance

\( J \) moment of inertia

\( p \) number of pole pairs

\( \omega_{r} \) rotor speed

\( \omega_{so} \) synchronous rotor speed

\( \omega_{ds} \) actual rotor speed

A. Stability analysis of induction motor

Stability analysis of induction motor alone can be studied by linearizing system (1) around an equilibrium operating point [5], the obtained system is:

\[
\begin{align*}
\frac{d}{dt} \delta \psi_{rd} &= -\frac{1}{\tau_r} \delta \psi_{rd} + \omega_{st} \delta \psi_{rd} + R_R \delta i_{sd} \\
\frac{d}{dt} \delta \psi_{sd} &= -\frac{1}{\tau_r} \delta \psi_{sd} + \omega_{st} \delta \psi_{sd} + \frac{1}{\tau_s} \delta i_{sd} + \omega_{st} \delta i_{sq} + \\
\frac{d}{dt} \delta \omega &= \frac{p^2}{J} \delta \omega \delta \omega.
\end{align*}
\]

With : \( \delta \psi_{rd} + j \delta \psi_{rd} = \delta \psi_{r} \), \( \delta i_{sd} + j \delta i_{sq} = \delta i_{s} \)

The state matrix corresponding to the state vector \( \delta x = [ \delta \psi_{rd}, \delta \psi_{sd}, \delta i_{sd}, \delta i_{sq}, \delta \omega ]^T \) is:

\[
A_o = \frac{1}{\tau_r} \begin{bmatrix}
-1 & \omega_{st} & L_M & 0 & 0 \\
-\omega_{st} & -1 & 0 & L_M & \tau_r \psi_{R} \\
1 & \frac{\tau_r}{\tau_s} \omega_{so} - \omega_{st} & \frac{\tau_r}{\tau_s} \omega_{so} & \frac{\tau_r}{\tau_s} \omega_{so} & 0 \\
-\frac{\tau_r}{\tau_s} \omega_{so} - \omega_{st} & \frac{1}{\tau_s} & -\tau_r \omega_{so} & \frac{\tau_r}{\tau_s} & \frac{\tau_r}{\tau_s} \psi_{R0} \\
\frac{p^2}{J} \psi_{R0} \omega_{so} & -\frac{p^2}{J} \psi_{R0} & 0 & \frac{p^2}{J} \psi_{R0} & 0
\end{bmatrix}
\]

With: \( \psi_{st} = \tau_r \omega_{st} \)

Ploting unstable eigen values (E.V) of the state matrix \( A_o \) permit localization of unstable regions in the torque speed plane as shown on figure (1).

Note that the line \( (D_l) \) is known as the unobservable line obtained in the case of DC excitation \( (\omega_{so} = 0) \).
B. Analytical expression of IM unstable regions

In order to establish analytical expression of stability limits, the following property is used

\[ \det(A_o) = \prod_{i=1}^{5} \lambda_i \]  

(4)

where \( \lambda_i \) are the eigen values of matrix \( A_o \), the system stability implies that the five eigen values must have a negative real part. Consequently, a condition of stability for system (3) is

\[ \det(A_o) < 0. \]  

(5)

The limit of stability is done by \( \det(A_o) = 0 \). Using Maple/Matlab and without any simplification, the expression find is

\[ \det(A_o) = \frac{B^2\psi R_o}{\pi^2 R R_J L_s} \left[ \omega_s^2 \left( R_s^2 + (L_s \omega_s)^2 \right) - \left( R_s^2 + (L_s \omega_s)^2 \right) \right] \]  

(6)

so:

\[ \omega_{sL_o} = \pm \frac{1}{\tau_f} \sqrt{ \frac{R_s^2 + (L_s \omega_s)^2}{R_s^2 + (L_s \omega_s)^2} } \]

These conditions of stability are represented in the torque/velocity plane by figure (2). It can be verified that unstable regions are the same as obtained previously with eigen values.

Fig. 2. Stability limits in the angular speed/torque plane

Fig. 3. Operating points

Fig. 4 and 5 show tries in quadrant I and II under load torque \( T_{L_o} = 9.3\text{N.m} \), for tow operating points \( s_1 \) and \( s_2 \), localized respectively in unstable and stable regions (figure 3).

Fig. 4. Tries in stable region (quadrant II): actual velocity (solid line), reference velocity (dashed line). \( \omega_{ref} = -100\text{rad/s} \), load torque \( T_{L_o} = 9.3\text{N.m} \)

Fig. 5. Tries in unstable region (quadrant II): actual velocity (solid line), reference velocity (dashed line). \( \omega_{ref} = -20\text{rad/s} \), load torque \( T_{L_o} = 9.3\text{N.m} \)

---

These conditions of stability are represented in the torque/velocity plane by figure (2). It can be verified that unstable regions are the same as obtained previously with eigen values.
III. OBSERVER DESIGN

The conventional full-order observer is defined by

\[
\begin{align*}
\frac{d}{dt}\hat{R} &= -(\frac{1}{\tau_r} + j\omega_i)\hat{R} + R_L\hat{L} + G_r\hat{e}_d \\
\frac{d}{dt}\hat{\omega}_r &= \frac{1}{\tau_r} + j\omega_i\hat{\omega}_r - \frac{1}{\tau_s} + j\omega_s\hat{L}_s + \frac{1}{L_s}\hat{u}_s + G_s\hat{e}_d \\
\frac{d}{dt}\hat{e}_d &= -K_{iw}\hat{e}_d - K_{p\omega}\frac{d}{dt}\hat{\omega}_e d, \quad \epsilon = 3 \left\{ e^{-j\phi}c_R\hat{E}_R \right\}
\end{align*}
\]

with:

\[e^{-j\phi} = \cos\phi - jsin\phi\]

\[G_r = \begin{bmatrix} g_{rd} & -g_{rq} \\ g_{rq} & g_{rd} \end{bmatrix}, \quad G_s = \begin{bmatrix} g_{sd} & -g_{sq} \\ g_{sq} & g_{sd} \end{bmatrix}\]

System obtained by linearizing observer model (7), and for \(\phi = 0\,\text{ls},\)

\[
\begin{align*}
\frac{d}{dt}\hat{\psi}_{Rd} &= -\frac{1}{\tau_r}\hat{\psi}_{Rd} + \omega_{ao}\hat{\psi}_{Ro} + R_L\hat{\psi}_{sd} \\
\frac{d}{dt}\hat{\psi}_{Ro} &= -\omega_{ao}\hat{\psi}_{Rd} - \frac{1}{\tau_r}\hat{\psi}_{Rd} + R_L\hat{\psi}_{sq} \\
\frac{d}{dt}\hat{\psi}_{sd} &= \frac{1}{L_s}\hat{\psi}_{Rd} + \frac{1}{L_s}\hat{\psi}_{sq} - \frac{1}{\tau_s}\hat{\psi}_{sd} \\
\frac{d}{dt}\hat{\psi}_{sq} &= -\omega_{ao}\hat{\psi}_{sd} + \hat{\psi}_{Rd} + \frac{1}{\tau_s}\hat{\psi}_{sd} \\
\frac{d}{dt}\hat{\psi}_{e} &= -K_{iw}\hat{\psi}_{ref}\hat{e}_iq - K_{p\omega}\hat{\psi}_{ref}(\omega_{ao}\hat{\psi}_{e} - \frac{1}{\tau_s}\hat{\psi}_{e} - \frac{1}{L_s}\hat{\psi}_{e}d + \frac{1}{L_s}\hat{\psi}_{e}o) \\
&\quad + \frac{1}{\tau_s}\hat{\psi}_{e}o\hat{e}_{\omega} \\
\end{align*}
\]

with: \(\hat{e}_{sd} = \hat{e}_{sdo} - \hat{e}_{sdo}, \hat{e}_{iq} = \hat{e}_{sqo} - \hat{e}_{sqo},\)

IV. GLOBAL STABILITY ANALYSIS

A new state vector \(\delta e\) is defined with:

\[
\delta e = \begin{bmatrix} \delta e_{r,\theta} & \delta e_{\psi_q} & \delta e_{\psi_d} & \delta e_{\psi_i} & \delta e_{\omega} \end{bmatrix}.
\]

The state matrix describing the estimation error is:

\[
\hat{A}_1 = \begin{bmatrix}
\frac{1}{\tau_r} & \omega_{ao} & -\frac{\omega_{ao}}{\tau_r} & 0 & \frac{1}{\tau_s} & -\frac{\omega_{ao}}{\tau_s} & \frac{\omega_{ao}}{\tau_r} + \frac{\omega_{ao}}{\tau_s} & 0 \\
-\frac{1}{\tau_r} & \frac{1}{\tau_s} & -\frac{1}{\tau_r} & -\frac{\omega_{ao}}{\tau_s} & \frac{1}{\tau_r} & -\frac{1}{\tau_s} & \frac{1}{\tau_r} & 0 \\
-\frac{\omega_{ao}}{\tau_r} & \frac{1}{\tau_s} & \frac{1}{\tau_r} & \frac{\omega_{ao}}{\tau_r} & -\frac{1}{\tau_r} & \frac{1}{\tau_s} & \frac{1}{\tau_s} & 0 \\
-\frac{1}{\tau_r} & \frac{1}{\tau_s} & \frac{1}{\tau_r} & \frac{1}{\tau_s} & -\frac{1}{\tau_r} & \frac{1}{\tau_s} & \frac{1}{\tau_s} & 0 \\
\end{bmatrix}
\]

with:

\[
\hat{A}_1(51) = -K_{p\omega}\omega_{ao}\hat{\psi}_{ref} \\
\hat{A}_1(52) = (K_{iw} - K_{p\omega})\hat{\psi}_{ref} \\
\hat{A}_1(53) = -K_{p\omega}\hat{\psi}_{ref} \\
\hat{A}_1(54) = \frac{K_{p\omega}\hat{\psi}_{ref}}{L_s\tau_r}
\]

\[
\hat{A}_1(55) = -\frac{K_{p\omega}\psi_{ref}^2}{L_s^2}
\]

To locate unstable zones, a representation of poles which have a positive real part is proposed. Figure (6) shows these zones for \(K_{iw} = 3000\), and different \(K_{p\omega}\).

\[
\begin{align*}
T_{Lo} = -\frac{\psi_{ref}^2}{L_s}\omega_{ao} \\
T_{Lo} = -\frac{\psi_{ref}^2}{L_s}(\frac{L_s + L_M}{\tau_r R_s + L_s + L_M})\omega_{ao}
\end{align*}
\]

These tow lines (figure 7) define the limits of unstable regions in regenerating mode whatever is \(K_{p\omega}\).
To validate these results, in figure (8) simulations are done when the induction motor is operating in regenerating mode. It is clear that as soon as the motor run across the boundary into the predicted unstable region, the sensorless system becomes unstable.

More precisely, a feedback gain superposing \((D_2)\) with \((D_1)\), must be calculated. Then, the unstable region will be limited to the line \((D_1)\) (Fig. 10). It can be noted that, whatever the structure of the matrix \(G\), \((D_1)\) is always defined by \(\omega_{so} = 0\). In this case the determinant may be expressed as:

\[
det(\hat{A}_1) = \alpha \omega_{so}^2
\]

V. Optimal Gain Design

The principle of the optimal instability reduction proposed here consists in the calculation of the feedback gain imposing the condition

\[
(D_1) = (D_2)
\]

The particular forms \(G_r = 0\) and \(G_s = \begin{bmatrix} g_{sd} & 0 \\ 0 & g_{sd} \end{bmatrix}\) are chosen.
This gives:

\[
\det(\hat{A}_1) = -\frac{k_{d2}^2 \omega_{ref}^2 \omega_s}{L_s \tau_s} \left[ \omega_{sd}(1 + \frac{\tau_s}{\tau_r} + g_{sd} \tau_s) - \omega_{id}(1 + \frac{\tau_s g_{sd}}{R_R + R_s}) \right] 
\]

(14)

To obtain form expressed by (13), we choose:

\[
g_{sd} = \frac{R_s}{L_s} 
\]

(15)

In order to validate the proposed design, simulations results are presented. In Fig. 11, the operating point is brought in the vicinity of \((D_1)\). This show that the unstability region is considerably reduced by the proposed gain design.

Fig. 11. Velocity transient in the vicinity of \((D_1)\) in regenerating mode (quadrant 2) (a), from \(T_{L_o} = 0 \ N.m\) to \(T_{L_o} = 7 \ N.m\) (c), low velocity \((\omega_o = 15 \ rad/s)\) (b), \(K_i = 3000, K_p = 300\).

Fig. 12 shows simulation results for tries at constant nominal torque in regenering mode. The operating point trajectory cross the line \((D_1)\) without unstability.

Fig. 12. Stable velocity transient crossing \((D_1)\), from \(P_1\) to \(P_2\), in regenerating mode (quadrant 4) (a), from \(\omega_o = 14.7 \ rad/s\) to \(\omega_o = 15.3 \ rad/s\) (b), nominal torque \((T_{L_o} = -7N.m)\) (c), \(K_i = 3000, K_p = 300\).

Fig. 13 illustrates simulation results for speed reverse under nominal torque. This figure shows that there is no loose of control, and estimator tracking capability is garanteed.

Fig. 13. Actual velocity (solid line), reference velocity (dashed line). Transition from stable to stable region crossing the line of unstability \((D_1)\).

VI. CONCLUSION

In this paper, stability of the speed sensorless vector control of induction motors is analysed. This allows to design an optimal feed back gain which can reduce the unstable zones to a line defined by DC excitation when all parameters are known. The gain obtained depend on motor parameters. These parameters change during motor operation due to temperature rise. Perspectives proposed is to study the stability of an extended adaptive observer which estimates rotor speed and stator resistance simultaneously.
