Intention Recognition using a Graph Representation

So-Jeong Youn, and Kyung-Whan Oh

Abstract—The human friendly interaction is the key function of a human-centered system. Over the years, it has received much attention to develop the convenient interaction through intention recognition. Intention recognition processes multimodal inputs including speech, face images, and body gestures. In this paper, we suggest a novel approach of intention recognition using a graph representation called Intention Graph. A concept of valid intention is proposed, as a target of intention recognition. Our approach has two phases: goal recognition phase and intention recognition phase. In the goal recognition phase, we generate an action graph based on the observed actions, and then the candidate goals and their plans are recognized. In the intention recognition phase, the intention is recognized with relevant goals and user profile. We show that the algorithm has polynomial time complexity. The intention graph is applied to a simple briefcase domain to test our model.

Keywords—Intention recognition, intention, graph, HCI.

I. INTRODUCTION

The design of a human-friendly system is a goal of Human-Computer Interaction (HCI) or Human-Robot Interaction (HRI). Many researchers make efforts to develop the convenient interaction providing natural language processing, voice recognition, and gesture recognition.

Recently, intention modeling and recognition are important research issues in HCI and HRI [1]. It is very important because the systems cannot support human adequately without knowing what the human wants to be done. Human can inform the system of his intention by text or speech explicitly. Also he can do it implicitly by doing something related his intention. It is easy for the system to understand the explicitly represented intentions like “copy this file” in HCI, or “open the window” in HRI. On the contrary, implicitly represented intentions might not be clear to the system. There have been many researches to handle this problem. We focus on the intention recognition by observing human behavior.

Intention modeling is an interesting research area and common issue to psychology and cognitive science. Some researches of computer science and robotics have shown good results by using the fruit of cognitive science, and psychology.

One of them is [2]. They used mental model of [3] and intent signal decomposition of [4] to suggest an intention reading model. They formulated an intention reading problem as a function of actions, tasks, and a psychico-mental state. The intention model in [2] is shown in Fig. 1. In [2], an intention has the same meaning as a goal.

As we can see in [2], an intention and a goal are used in the same way in an intention or a goal recognition problem. A goal is usually a conjunction of subgoals, and has a hierarchical structure. There are some ambiguities interpreting what is the final target or goal when a system recognizes a goal. Is this enough to describe user intention? Or is there another goal which is in deeper abstraction level? Therefore, we decide to use the term goal and intention in different meaning. A goal is something that a human hopes to achieve. That is, a goal is the desired state of affairs of a human and is the result of a sequence of actions. An intention is an idea or a mental state of what a human is going to do. If a man has in mind to quit smoking, that is an intention. But if he decides to quit smoking to change himself in the New Year, that is a goal. After he makes an action plan, he can achieve the goal doing actions sequentially. This process is shown in Fig. 2.

Intention recognition is a reverse process of the behavior generation. At first, human actions are observed. Then, a goal can be recognized through observed actions. With the achieved goal, we can recognize human intention under context.
In this paper, we suggest a method of recognizing intention by observing user’s behavior, finding relevant goals, and considering current context. In this method, we represent the relations among the intention, goal, and actions as a graph to recognize intention. We call this representation **Intention Graph**.

Intention graph is inspired by Goal Graph in [5] and Graphplan in [6]. Blum suggests a new approach to planning based on compact structure, Graphplan. Jun Hong improves it to recognize fully and partially achieved goals and apply it to large scale Unix domain which has 100,000 goals. We improve Jun Hong’s Goal Graph to recognize intentions using recognized goals and user profile, and apply it to modified briefcase domain.

The structure of this paper is as follows: Section II defines an Intention Graph and few concepts used in our graph. In section III, five algorithms are suggested to recognize intentions based on Intention Graph. Section IV shows a briefcase domain with Intention Graph. In this domain, we define some goals, intentions, and user profile information. We will give a brief conclusion in section V.

II. INTENTION GRAPH

A. Organization of Intention Graph

Intention graph consists of state, action, goal, and intention nodes and edges. It is represented as $IG = <S, A, G, I, E>$ where $S$ is a set of state node, $A$ is a set of action node, $G$ is a set of goal node, $I$ is a set of intention node, and $E$ is a set of edges.

$S_t$ is a state set at time step $t$. Each state node represents a ground literal which values are True. The negative literal $\neg P$ can be used as a state. The closed-world assumption is used, meaning that any conditions that are not mentioned in a state are assumed false. A special subset of $S$ is a set of initial states and is denoted as $S_0$. We assume that the initial states are given completely.

An instance of action schema consists of a set of preconditions and a set of effects. A precondition set is a conjunction of positive literals stating what must be true in a state before the action can be executed. An effect set is a conjunction of literals describing how the state changes when the action is executed.

An instance of a goal schema consists of desired states, and they are called goal descriptions. An instance of an intention schema consists of ground goal conditions and related user profile information. Each edge represents the relations between nodes. An example of intention graph is shown in Fig. 3.

Intention graph has three layers: Action layer has action nodes, proposition layer has state nodes including states for user profile information, and goal & intention layer has recognized goal and intention nodes. There is one action node in each time step. New time step starts when an action is observed.

A state node at time $t$ is represented as $state(s, t)$ where $s$ is a ground literal. The initial state is $state(s, 0)$. An action node is represented by $action(a, t)$ where $a$ is an observed action at time $t$. A goal node is represented by $goal(g, t)$ where $g$ is a goal recognized at time $t$. An intention node is represented by $intention(i, t)$ where $i$ is an intention. There are six kinds of edges in intention graph. A precondition edge connects an action node with its precondition state node and is represented by $precondition-edge(state(s, t), action(a, t+1))$. An effect edge connects an action node with the state node which is the result of the action and is represented by $effect-edge(action(a, t), state(s, t))$. A goal description edge which is represented by $goal-d-edge(state(s, t), goal(g, t))$ connects one of goal description states with the goal. An inference edge is represented by $inference-edge(goal(g, t), intention(i, t))$ and it connects an intention node with its related user profile state node. An inference edge is represented by $inference-edge(goal(g, t), intention(i, t))$ and it connects a goal node with its intention node. A persistence edge is represented by $persistence-edge(state(s, t-1), state(s, t))$ and makes it possible to preserve a state which doesn’t conflict with the effect of an observed action.

B. Definition of Valid Intention

To resolve intention recognition problem using intention graph, we define some useful concepts.

Definition 1: causal link

Let $a_i$ and $a_j$ be two observed actions at time steps $i$ and $j$ respectively, where $i < j$. There exists a causal link between $a_i$ and $a_j$, written as $a_i \rightarrow a_j$, if and only if one of the effects of $a_i$ satisfies one of the preconditions of $a_j$.

An example is shown in Fig. 4. The effect of observed action $a_i$ is $s_1$ and the precondition of observed action $a_j$ is also $s_1$. So, there is a causal link between $a_i$ and $a_j$. This concept can be extended to goal. In Fig. 4, the effect of $a_2$ is the goal description of $g_3$. In this case, we define a causal link between $a_2$ and $g_3$ and write $a_2 \rightarrow g_3$.

Definition 2: causal link path between action and goal

Given an intention graph, let $a_i$ be an action observed at time step $i$ and $g_j$ be a goal fully achieved in time step $j$, where $i < j$. A path that connects $a_i$ to $g_j$ via one or more precondition edge, effect edge, zero or more persistence edge, and a description edge, is called a causal link path between $a_i$ and $g_j$.

Causal link path is defined between two nodes those are not adjacent. For instance, in Fig. 4, there exists a causal link path between $a_3$ and $g_2$. 

![Fig. 3 An Example of Intention Graph](image-url)
Definition 3: valid plan

Let \( g \) be a goal, and \( P = \langle A, O, L \rangle \), where \( A \) is a set of observed actions, \( O \) is a set of temporal ordering constraints, \( \{a_i < a_j\} \), over \( A \), and \( L \) is a set of causal links, \( \{a_i \rightarrow a_j\} \), over \( A \).

Let \( S \) be the initial states. \( P \) is a valid plan for \( g \) given \( S \), if and only if

1. the actions in \( A \) can be executed in \( S \) in any order consistent with \( O \);
2. the goal \( g \) is fully achieved after the actions in \( A \) are executed in \( S \) in any order consistent with \( O \).

An example is shown in Fig. 5. An initial state is \( S_0 \) observed action set is \( \{a_1, a_2\} \) and goal is achieved after \( a_1 \) and \( a_2 \) are executed. Then, \( P = \langle\{a_1, a_2\}, \{a_1 < a_2\}, \{a_1 \rightarrow a_2, a_2 \rightarrow g_2\}\rangle \) is a valid plan for \( g_2 \).

Definition 4: relevant goal

Given a intention \( i \), a goal \( g \) is a relevant goal for \( i \) if and only if there exists a causal link between \( g \) and \( i \).

For instance, in the example shown in Fig. 5, the goal \( g_2 \) is the relevant goal of \( i_2 \). There exists a causal link between goal \( g_2 \) and intention \( i_2 \), if and only if a goal \( g_2 \) is one of the goal condition of intention \( i_2 \).

Definition 5: valid intention

Let \( G \) be a set of relevant goals for intention \( i \), \( A_i \) be a set of observed actions, and \( P_i = \langle A_i, O_i, L_i \rangle \) be a valid plan for each \( g \) in \( G \). Then, \( i \) is a valid intention if and only if

1. \( A = \bigcup_{i=1}^{n} A_i \) where \( n = |G| \)
2. \( A = A_0 \)

For instance, in the example shown in Fig. 6, \( A_1 = \{a_1, a_2\}, A_2 = \{a_1, a_2\}, \) and \( A_1 \cup A_2 = A_i \). So, \( i \) is valid intention because the valid plans of its relevant goals cover observed action set.

Fig. 4 An Example of Causal Link and Causal Link Path

Fig. 5 An Example of Valid Plan and Relevant Goal

Fig. 6 An Example of Valid Intention

Fig. 7 Goal Extension Algorithm
If action \( a \) is observed at time \( t \), the action extension algorithm makes a node \( action(a, t) \) and adds an edge of precondition-edge \((state(s, t-1), action(a, t))\). The algorithm adds an effect state node \( state(e, t) \) for all effects of action \( a \) and adds effect-edge \((action(a, t), state(e, t))\). If \( state(s, t-1) \) does not conflict with any \( effect(e, t) \), algorithm adds the same state node \( state(s, t) \) in time \( t \), and connects \( state(s, t-1) \) to \( state(s, t) \) with persistence-edge \((state(s, t-1), state(s, t))\).

Fig. 8 Action Extension Algorithm

After last action is processed, the graph is analyzed and proper goals and their valid plans are recognized. A GoalPlan-Recognition algorithm has two parts. At first, redundant goals are pruned. If a goal \( g_t \) at time step \( t \) has no causal link with action at \( t \), its goal descriptions are the states from previous time step. If they were not initial states, they actually were results of an action at time \( k \) where \( k < t \). Then there is a goal \( g_{k+1} \) which is the same with \( g_t \). The goal \( g_t \) is a redundant goal of \( g_{k+1} \).

At the second part, the algorithm finds a valid plan following the causal links for each remaining goal. The algorithm returns with GoalPlan list.

B. Intention Recognition Phase

This phase has two steps: intention extension step, graph analysis step. In the first step, intention-extension algorithm gets goal conditions and user profile conditions for each intention schema in schemata set. If all goal conditions are in the recognized goal set and user profile conditions are in current context, then the algorithm adds intention node \( intent(l, n+1) \), and new state node \( state(uc, n+1) \). Also, the algorithm adds reference edge reference-edge \((state(uc, n+1), intent(l, n+1))\) to connects user profile state node to intention node, and adds inference edges inference-edge \((goal(gc, k), intent(l, n+1))\) to connect every relevant goal node to intention node.

Fig. 9 Goal and its Plan Recognition Algorithm

In the second step, the intent-recognition algorithm gets a set of relevant goals for each intention in an intention schema set. \( A^{'}_I \) is a union set of all actions in valid plans of relevant goals. If \( A^{'}_I \) is same with observed action set \( A_o \), \( I \) is the valid intention.

Fig. 10 Intention Extension Algorithm

Fig. 11 Intention Recognition Algorithm
The algorithm returns with the valid intention lists.

C. Algorithm Complexity

Our algorithms have polynomial size and time complexity. The first 3 algorithms are based on Jun Hong’s Goal Graph algorithm, and it is proved polynomial size and time in [5]. Therefore we prove intention recognition phase algorithm in this section.

Theorem 1: (polynomial time and space)
Consider an intention recognition problem with \( l_a \) observed actions, a finite number of object instance at each time step. Let \( n \) be the number of object instance, \( l_i \) be the number of intentions in intention schema set, \( l_g \) be the number of goals in goal schema set, \( m_o \) be the maximum number of relevant goals of an intention, \( m_r \) be the maximum number of user condition of an intention, and \( m_g \) be the maximum number of goal condition. Then, the space size of the intention graph and time needed to recognize all valid intention are polynomial in \( l_a, l_i, m_r, m_u, m_g, \) and \( n \).

Proof.
The maximum number of intention nodes is \( l_i \cdot n \), because there can be no same intention node in the intention graph generated by intention-extension algorithm. The number of user condition node is \( m_u \cdot l_i \), and the number of edges is \( (m_g + m_u) \cdot l_i \). Since the intention recognition algorithm adds no nodes and edges, the space size of our algorithm is \( O((1 + m_g + 2m_u) \cdot l_i) \).

The time complexity is \( O((1 + m_g + 2m_u) \cdot l_i) \).

IV. BRIEFCASE DOMAIN

We apply Intention Graph to briefcase domain [7]. It is modified to include intention and user profile information. The modified problem is shown in Table 1. Physical objects packing in the briefcase can be transferred between three places. User profile can be any kind of information in any representation. As user profile representation is not our issues, we use user’s occupations in text style.

There are four kinds of action schema, goal schema, and intention schema. Schema examples are shown in Fig. 12. Action and goal can have parameters. An action schema has preconditions and effects. A goal schema contains desired states. An intent schema has its goal condition and user condition.

\begin{table}[h]
\centering
\caption{BRIEFCASE DOMAIN EXPLANATION}
\begin{tabular}{|l|l|}
\hline
\textbf{Classification} & \textbf{Value} \\
\hline
Physical object & a briefcase, a dictionary, a checkbook, a pencil \\
Places & home, office, shop \\
Action Schemata & . Moving the briefcase from one location to another \\
Schemata & . Putting a physical object in the briefcase \\
Goal Schemata & . Taking out a physical object from the briefcase \\
Schemata & . Printing a check \\
Intention Schemata & . Keeping a physical object at a location \\
Schemata & . Printing a check for a person \\
User Profile & . He/She would like to come home from work \\
\hline
\end{tabular}
\end{table}

In this domain, a physical object \textit{briefcase} is instantiated as \text{B}, a place \textit{home} as \text{H}, a place \textit{office} as \text{O}, and a dictionary as \text{D}. The initial states are given as \{at \text{B H}, at \text{D H}\} and actions are observed in the sequence of \{\text{put_in D H, move B H O, take_out D}\}. After graph construction step finish in goal recognition phase, the intention graph has 9 goal nodes. During the goal pruning step, 6 goals are removed. With the three goals and its valid plans, our algorithms find valid intentions during intention recognition phase. The results graph is shown in Fig 14.
complexity. The algorithm has polynomial time and space based on relevant goals and user profile information under graph is analyzed. And then, valid intentions are recognized and its state nodes. After observing actions is finished, the GraphPlan. The Intention Graph is extended by action nodes intention graph. It is inspired by the idea of Goal Graph and proposed an approach to recognize valid intentions using issues.

Two or more actions can be happen in the real world, especially action can be observed at a time step in the Intention Graph. Vague, but we can’t handle it. Another weakness is that just one closed world assumption. Some information could be missed or most obvious defect of the prior model is that it considers remains to be done before it can be considered complete. The international Scholarly and Scientific Research & Innovation 1(1) 2007

Although the work reported here is encouraging, much remains to be done before it can be considered complete. The most obvious defect of the prior model is that it considers closed world assumption. Some information could be missed or vague, but we can’t handle it. Another weakness is that just one action can be observed at a time step in the Intention Graph. Two or more actions can be happen in the real world, especially HRI domain. Work is currently under way to address these issues.

V. CONCLUSION

We have discussed intention recognition problem and have proposed an approach to recognize valid intentions using intention graph. It is inspired by the idea of Goal Graph and GraphPlan. The Intention Graph is extended by action nodes and its effect sate nodes. After observing actions is finished, the graph is analyzed. And then, valid intentions are recognized based on relevant goals and user profile information under current context. The algorithm has polynomial time and space complexity.

Although the work reported here is encouraging, much remains to be done before it can be considered complete. The most obvious defect of the prior model is that it considers closed world assumption. Some information could be missed or vague, but we can’t handle it. Another weakness is that just one action can be observed at a time step in the Intention Graph. Two or more actions can be happen in the real world, especially HRI domain. Work is currently under way to address these issues.
