Piecewise Interpolation Filter
for Effective Processing of Large Signal Sets

Anatoli Torokhti and Stanley Miklavcic

Abstract—Suppose \( K_y \) and \( K_x \) are large sets of observed and reference signals, respectively, each containing \( N \) signals. Is it possible to construct a filter \( F: K_y \rightarrow K_x \) that requires a priori information only on few signals, \( p \ll N \), from \( K_y \) but performs better than the known filters based on a priori information on every reference signal from \( K_y \)? It is shown that the positive answer is achievable under quite unrestrictive assumptions. The device behind the proposed method is based on a special extension of the piecewise linear interpolation technique to the case of random signal sets. The proposed technique provides a single filter to process any signal from the arbitrarily large signal set. The filter is determined in terms of pseudo-inverse matrices so that it always exists.

Keywords—Wiener filter, filtering of stochastic signals.

I. INTRODUCTION

A. Motivations

The problem under consideration is motivated by the following observations.

1) Filtering of Large Sets of Signals; Less Initial Information for Better Filtering: Suppose we need to transform a set of signals \( K_y \) to another set of signals \( K_x \). The signals are represented by finite random vectors. A major difficulty and inconvenience common to many known filtering methodologies (see, for example, [2]–[10], [12], [14], [23], [24], [26]) is that they require a priori information on each reference signal to be estimated. In particular, the filters in [23], [24], [26] are based on the use of either the reference signal \( x \in K_x \) itself, as in [23], [24], or its estimate, as in [26]. The Wiener filtering approach (see, for example, [2]–[14], [24], [26]) assumes that a covariance matrix formed from a reference signal, \( x \in K_x \), and an observed signal, \( y \in K_y \), is known or can be estimated. The latter can be done, for instance, from samples of \( x \) and \( y \). In particular, this means that the reference signal \( x \) can be measured.

In the case of processing large signal sets, such restrictions become much more inconvenient. The major motivating question for this work is as follows. Let \( \mathcal{F}: K_y \rightarrow K_x \) denote a filter that estimates a large set of reference signals, \( K_y \), from a large set of observed signals, \( K_x \). Each set contains \( N \) signals. Is it possible to construct a filter \( \mathcal{F} \) that requires a priori information only on few signals, \( p \ll N \), from \( K_y \) but performs better than the known filters based on a priori information on every reference signal from \( K_y \)? We denote such a filter by \( \mathcal{F}^{(p \ll 1)} \).

It is shown in Sections II-C and IV-D that the positive answer is achievable under quite unrestrictive assumptions. The required features of filter \( \mathcal{F}^{(p \ll 1)} \) are satisfied by its special structure described in Sections II-C, III-A and III-D. The related conditions are also considered in those Sections.

2) Filtering Based on Idea of Piecewise Function Interpolation: The specific structure of the proposed filter follows from the extension of piecewise function interpolation [15]. This is because the technique of piecewise function interpolation [15] has significant advantages over the methods of linear and polynomial approximation used in known filtering techniques (such as, for example, those in [6], [10]).

The structure of the proposed filter is presented in Sections II-C, III-A and IV-B below.

3) Exploiting Pseudo-Inverse Matrices in the Filter Model: Most of the known filtering techniques, for example, those ones in [2]–[4], [7]–[9], [12], [24], [26], are based on exploiting inverse matrices in their mathematical models. In the cases of grossly corrupted signals or erroneous measurements those inverse matrices may not exist and, thus, those filters cannot be applied.

The filter proposed here avoids this drawback since its model is based on exploiting pseudo-inverse matrices. As a result, the proposed filter always exist. That is, it processes any kind of noisy signals. An extension of the filtering techniques to the case of implementation of the pseudo-inverse matrices is done on the basis of theory presented in [6].

4) Computational Work: Let \( m \) and \( n \) be the number of components of \( x \in K_x \) and of \( y \in K_y \), respectively, where \( K_x \) and \( K_y \) each contains \( N \) signals. The known filtering techniques (e.g. see [2]–[9], [12], [24], [26]), applied to \( x \) and \( y \), require the computation of a product of an \( m \times n \)
matrix and an $n \times n$ matrix, as well as the computation of an $n \times n$ inverse or pseudo-inverse matrix for each pair of signals $x \in K_x$ and $y \in K_y$. This requires $O(2mn^2)$ and $O(26n^3)$ flops, respectively, [27]. Thus, for the processing of all signals in $K_x$ and $K_y$, the filters in [2]–[9], [12], [24], [26] require $O(2mn^2N) + O(26n^3N)$ operations.

Alternatively, $K_x$ and $K_y$ can be represented by vectors, $\chi$ and $\gamma$, each with $mN$ and $nN$ components, respectively. In such a case, the techniques in [2]–[9], [12], [24], [26] can be applied to $\chi$ and $\gamma$ as opposed to each signals in $K_x$ and $K_y$. The computational requirement is then $O(2mn^2N^2)$ and $O(26n^3N^3)$ operations, respectively [27].

In both cases, but especially when $N$ is large, the computational work associated with the approaches [2]–[9], [12], [24], [26] becomes unreasonable hard.

For the filter $\mathcal{F}^{(p-1)}$ to be introduced below, the associated computational work is substantially less. This is because $\mathcal{F}^{(p-1)}$ requires the computation of only $p$ pseudo-inverse matrices associated with $p$ selected signals in $K_x$, where $p$ is much less than the number of signals in $K_x$. Therefore, for processing of the signal sets, $K_x$ and $K_y$, $\mathcal{F}^{(p-1)}$ requires only $O(2mn^2p) + O(26n^3p)$ flops where $p \ll N$.

C. Relevant works

Some particular filtering techniques relevant to the method proposed below are as follows.

1) GENERIC OPTIMAL LINEAR (GOL) FILTER [6]: The generic optimal linear (GOL) filter in [6] is a generalization of the Wiener filter to the case when covariance matrix is not invertible and observable signal is arbitrarily noisy (i.e. when, in particular, noise is not necessarily additive and Gaussian). The GOL filter has been developed for processing an individual stochastic signal. Some ideas from [6] are used in the proof of Theorem 1 below.

2) SIMPLICIAL CANONICAL PIECEWISE LINEAR FILTER [24]: A complex Wiener adaptive filter was developed in [24] from the two-dimensional complex-valued simplicial canonical piecewise linear filter [25]. The filter in [24] was developed for the processing of an individual stochastic signal and can be exploited when the reference signal is known and a ‘covariance-like’ matrix is invertible. The latter precludes an application to the signal types when the matrices used in [24] are not invertible for the signals. Similarly, the filters studied in [9], [12] were developed for the processing of a single signal when the covariance matrices are invertible.

For the filter proposed here, these restrictions are removed.

3) ADAPTIVE PIECEWISE LINEAR FILTER [23]: A piecewise linear filter in [23] was proposed for a fixed image denoising (given by a matrix), corrupted by an additive Gaussian noise. That is, the method involved a non stochastic reference signal and required its knowledge. No theoretical justification for the filter was given in [23].

4) AVERAGING POLYNOMIAL FILTER [11], [13]: The averaging polynomial filter proposed in [11], [13] was developed for the purpose of processing infinite signal sets. The filter was based on an argument involving the ‘averaging’ over sets of signals under consideration. This device allows one to determine a single filter for the processing of infinite signal sets. At the same time, it leads to an increase in the associated error when signals differ considerably from each other.

5) OTHER RELEVANT FILTERS: The technique developed in [14] is an extension of the GOL filter to the constraint problem with respect to the filter rank. It concerns data compression.

The methods in [7], [8], [16], [17] have been developed for deterministic signals. Motivated by the results achieved in [16], [17], adaptive filters were elaborated in [18]. A theoretical basis for the device proposed in [16], [17] is provided in [19].

We note that the idea of piecewise linear filtering has been used in the literature in several very different conceptual frameworks, despite exploiting some very similar terms (as in [16]–[25]). At the same time, a common feature of those techniques is that they were developed for the processing of a single signal, not of large signal sets as in this paper. In particular, piecewise linear filters in [20] have been obtained by arranging linear filters and thresholds in a tree structure. Piecewise linear filters discussed in [21] were developed using so-called threshold decomposition, which is a segmentation operator exploited to split a signal into a set of multilevel components. Filter design methods for piecewise linear systems proposed in [22] were based on a piecewise Lyapunov function.

D. Difficulties associated with the known filtering techniques

Basic difficulties associated with applying the known filtering techniques to the case under consideration (i.e. to processing of large signal sets, $K_x$ and $K_y$) are that:

(i) they require an information on each reference signal (in the form of a sample, for example),

(ii) matrices used in the known filters can be not invertible and then the filter does not exist, and

(iii) the associated computation work may require a very long time. MATLAB can be out of memory for computing the GOL filter [6] when each of sets $K_x$ and $K_y$ is represented by a long vector (this option has been discussed in Section I-B4 above).

E. Differences from the known filtering techniques

The differences from the known filtering techniques discussed above are as follows.

(i) We consider a single filter that processes arbitrarily large input-output sets of stochastic signal-vectors. The known filters [2]–[10], [12], [14], [16]–[26] have been developed for the processing of an individual signal-vector only. In the case of their application to arbitrarily large signal sets, they imply difficulties described in Sections I-B and I-D above.

(ii) As a result, our piecewise linear filter model (Section III), the statement of the problem (Section III-C below) and consequently, the device of its solution (Section IV below) are different from those considered in [16]–[25]. In this regard, see also Section I-C5.

(iii) The above naturally leads to a new structure of the filter (presented in Sections III-D and IV-B below) which is very different from the known ones.
F. Contribution

In general, for the processing of large data sets, the proposed filter allows us to achieve better results in comparison with the known techniques in [2]-[20]. In particular, it allows us to:

(i) achieve a desired accuracy in signal estimation3,
(ii) exploit a priori information only on few reference signals, p, from the set $K_x$ that contains $N \gg p$ signals or even infinite number of signals,
(iii) find a single filter to process any signal from the arbitrarily large signal set,
(iv) determine the filter in terms of pseudo-inverse matrices so that the filter always exists, and
(v) decrease the computational load compared to the related known techniques.

II. SOME PRELIMINARIES

A. Notation

The signal sets we consider are, in fact, special representations of time series.

Let $(\Omega, \Sigma, \mu)$ be a probability space4, and $K_x$ and $K_y$ be arbitrarily large sets of signals such that

$$K_x = \{x(t, \cdot) \in L^2(\Omega, \mathbb{R}^m) \mid t \in T\}$$

and

$$K_y = \{y(t, \cdot) \in L^2(\Omega, \mathbb{R}^n) \mid t \in T\}$$

where $T := [a, b] \subseteq \mathbb{R}$. We interpret $x(t, \cdot)$ as a reference signal and $y(t, \cdot)$ as an observable signal, an input to the filter $\mathcal{F}$ studied below5. The variable $t \in T \subseteq \mathbb{R}$ represents time6. Then, for example, the random signal $x(t, \cdot)$ can be interpreted as an arbitrary stationary time series.

Let $\{t_k\}_1^n \subset T$ be a sequence of fixed time-points such that

$$a = t_1 < \ldots < t_p = b. \quad (1)$$

Because of the partition (1), the sets $K_x$ and $K_y$ are divided in ‘smaller’ subsets $K_{x,j}, \ldots, K_{x,p-1}$ and $K_{y,1}, \ldots, K_{y,p-1}$, respectively, so that, for each $j = 1, \ldots, p$,

$$K_{x,j} = \{x(t, \cdot) \mid t_j \leq t \leq t_{j+1}\} \quad (2)$$

$$K_{y,j} = \{y(t, \cdot) \mid t_j \leq t \leq t_{j+1}\}. \quad (3)$$

Therefore, $K_x$ and $K_y$ can now be represented as $K_x = \bigcup_{j=1}^{p-1} K_{x,j}$ and $K_y = \bigcup_{j=1}^{p-1} K_{y,j}$.

3This means that any desired accuracy is achieved theoretically, as is shown in Section IV-D below. In practice, of course, the accuracy is increased to a prescribed reasonable level.

4As usually, $\Omega = \{\omega\}$ is the set of outcomes, $\Sigma$ is a σ-field of measurable subsets in $\Omega$ and $\mu: \Sigma \to [0, 1]$ an associated probability measure on $\Sigma$. In particular, $\mu(\Omega) = 1$.

5In an intuitive way $y$ can be regarded as a noise-corrupted version of $x$. For example, $y$ can be interpreted as $y = x + n$ where $n$ is white noise. In this paper, we do not restrict ourselves to this simplest version of $y$ and assume that the dependance of $y$ on $n$ and $n$ is arbitrary.

6More generally, $T$ can be considered as a set of parameter vectors $\alpha = (\alpha^{(0)}, \ldots, \alpha^{(m)}) \in \mathbb{C}^q \subset \mathbb{R}^q$, where $\mathbb{C}^q$ is a q-dimensional cube, i.e., $y = y(\alpha, \cdot)$ and $x = x(\alpha, \cdot)$. One coordinate, say $\alpha^{(1)}$ of $\alpha$, could be interpreted as time.

B. Brief description of the problem

Given two arbitrarily large sets of random signals, $K_x$ and $K_y$, find a single filter $\mathcal{F}: K_x \to K_y$ that estimates the signal $x \in K_x$ with a controlled, associated error. Note that in our formulation the set $K_y$ can be finite or infinite.

C. Brief description of the method

The solution of the above problem is based on the representation of the proposed filter in the form of a sum with $p-1$ terms $\mathcal{F}_1, \ldots, \mathcal{F}_{p-1}$ where each term, $\mathcal{F}_j$, is interpreted as a particular sub-filter (see (4) and (5) below). Such a filter is denoted by $\mathcal{F}^{(p-1)}: K_y \to K_x$.

The sub-filter $\mathcal{F}_j$ transforms signals that belong to ‘piece’ $K_{Y,j}$ of set $K_y$ to signals in ‘piece’ $K_{X,j}$ of $K_x$, i.e. $\mathcal{F}_j : K_{Y,j} \to K_{X,j}$. Each sub-filter $\mathcal{F}_j$ depends on two parameters, $\alpha_j$ and $B_j$.

The prime idea is to determine $\mathcal{F}_j$ (i.e. $\alpha_j$ and $B_j$) separately, for each $j = 1, \ldots, p-1$. The required $\alpha_j$ and $B_j$ follow from the solutions of the equation (12) and an associated minimization problem (12) (see Sections III-D and IV-B below). This procedure adjusts $\mathcal{F}_j$ so that the error associated with the estimation of $x(t, \cdot) \in K_{X,j}$ is minimal.

A motivation for such a structure of the filter $\mathcal{F}^{(p-1)}$ is as follows. The method of determining $\alpha_j$ and $B_j$ provides an estimate $\mathcal{F}_j[y(t, \cdot)]$ that interpolates $x(t, \cdot) \in K_{X,j}$ at $t = t_j$ and $t = t_{j+1}$. In other words, the filter is flexible to variations in the sets of observed and reference signals $K_Y$ and $K_X$, respective. Due to this way of determining $\mathcal{F}_j$, it is natural to expect that the processing of a ‘smaller’ signal set, $K_{Y,j}$, may lead to a smaller associated error than that for the processing of the whole set $K_y$ by a filter which is not specifically adjusted to each particular piece $K_{X,j}$.

As a result, $\mathcal{F}^{(p-1)}[y(t, \cdot)]$ represents a special piecewise interpolation procedure and, thus, should be attributed with the associated advantages such as, for example, the high accuracy of estimation.

In Section IV-D, this observation is confirmed. In Section IV-E, it is also shown that the proposed technique allows us to avoid the difficulties discussed in Section I-D above.

III. DESCRIPTION OF THE PROBLEM

A. Piecewise linear filter model

Let $\mathcal{F}^{(p-1)}: K_y \to K_x$ be a filter such that, for each $t \in T$,

$$\mathcal{F}^{(p-1)}[y(t, \cdot)] = \sum_{j=1}^{p-1} \delta_j \mathcal{F}_j[y(t, \cdot)] \quad (4)$$

where

$$\mathcal{F}_j[y(t, \cdot)] = \alpha_j + B_j[y(t, \cdot)] \quad (5)$$

and

$$\delta_j = \begin{cases} 1, & \text{if } t_j \leq t \leq t_{j+1}, \\ 0, & \text{otherwise}. \end{cases}$$

Here, $\mathcal{F}_j$ is a sub-filter defined for $t_j \leq t \leq t_{j+1}$. In (5), $\alpha_j = [\alpha_j^{(1)}, \ldots, \alpha_j^{(m)}] \in \mathbb{R}^m$ and $B_j : L^2(\Omega, \mathbb{R}^n) \to L^2(\Omega, \mathbb{R}^m)$ is a linear operator given by a matrix $B_j \in \mathbb{R}^{m \times n}$, so that

$$[B_j(y)](t, \omega) = B_j[y(t, \omega)].$$
Thus, $F_j$ is defined by a matrix $F_j \in \mathbb{R}^{m \times n}$ such that
\[ F_j[y(t, \omega)] = \alpha_j + B_j[y(t, \omega)]. \tag{6} \]

Filter $F^{(p-1)}$ defined by (4)–(6) is called the piecewise filter\(^7\).

B. Assumptions

In the known approaches related to filtering of stochastic signals (e.g. see \cite{2}–\cite{14}, \cite{24}, \cite{26}), it is assumed that covariance matrices formed from the reference signal and observed signal are known or can be estimated.

The assumption used here is similar. The covariance matrices that are assumed to be known or can be estimated, are formed from selected signal pairs $\{x(t_j, \cdot), y(t_j, \cdot)\}$ with $j = 1, \ldots, p$ to a small number\(^8\), $p \ll N$, where $N$ is the number of signals in $K_x$ or $K_y$.

C. The problem

In (4)–(6), parameters of the filter $F^{(p-1)}$, i.e. vector $\alpha_j$ and matrix $B_j$, for $j = 1, \ldots, p-1$, are unknown. Therefore, under the assumptions described in Section III-B, the problem is to determine $\alpha_j$ and $B_j$, for $j = 1, \ldots, p-1$. The related problem is to estimate an error associated with the filter $F^{(p-1)}$.

Solutions to the both problems are given in Sections IV-B and IV-D, respectively. In particular, in the following Section III-D, interpolation conditions (8) and (12) are introduced that lead to a determination of $\alpha_j$ and $B_j$.

D. Interpolation conditions

Let us denote
\[ \|x(t_j, \cdot)\|^2_{\Omega} = \int_\Omega \|x(t_j, \omega)\|^2 d\mu(\omega) \tag{7} \]
where $\|x(t_j, \omega)\|_2$ is the Euclidean norm of $x(t_j, \omega) \in \mathbb{R}^m$.

For $t = t_1$, let $\hat{x}(t_1, \cdot)$ be an estimate of $x(t_1, \cdot)$ determined by known methods \cite{2}–\cite{14}, \cite{24}, \cite{26}. This is the initial condition of the proposed technique.

For $j = 1, \ldots, p-1$, each sub-filter $F_j$ in (5)–(6) is defined so that $\alpha_j$ and $B_j$ satisfy the conditions as follows.

Sub-filter $F_1$: For $j = 1$, $\alpha_1$ and $B_1$ solve
\[ \hat{x}(t_1, \cdot) = \alpha_1 + B_1[y(t_1, \cdot)] \quad \text{and} \quad \min ||[x(t_2, \cdot) - \alpha_1] - B_1[y(t_2, \cdot)]||^2_2, \tag{8} \]
respectively. Then an estimate of $x(t, \cdot)$, $\hat{x}(t, \cdot)$, for $t \in [t_1, t_2]$, is defined as
\[ \hat{x}(t, \cdot) = F_1[y(t, \cdot)] = \hat{x}(t_1, \cdot) + B_1[y(t, \cdot) - y(t_1, \cdot)] \tag{10} \]
where $\alpha_1$ and $B_1$ satisfy (8). In particular, $\alpha_1 = \hat{x}(t_1, \cdot) - B_1[y(t_1, \cdot)]$ and
\[ \hat{x}(t_2, \cdot) = F_1[y(t_2, \cdot)]. \tag{11} \]

Extending this procedure up to $j = k - 1$, where $k = 3, \ldots, p$, we set the following. Let $\hat{x}(t_{k-1}, \cdot)$ be an estimate of $x(t_{k-1}, \cdot)$ defined by the preceding steps as
\[ \hat{x}(t_{k-1}, \cdot) = F_{k-2}[y(t_{k-1}, \cdot)]. \tag{11} \]

Then sub-filter $F_{k-1}$ is defined as follows.

Sub-filter $F_{k-1}$: For $j = k-1$, $\alpha_{k-1}$ and $B_{k-1}$ solve
\[ \hat{x}(t_{k-1}, \cdot) = \alpha_{k-1} + B_{k-1}[y(t_{k-1}, \cdot)] \quad \text{and} \quad \min \|[x(t, \cdot) - \alpha_{k-1}] - B_{k-1}[y(t, \cdot)]||^2_2, \tag{12} \]
respectively. Then an estimate of $x(t, \cdot)$, $\hat{x}(t, \cdot)$, for $t \in [t_{k-1}, t_k]$ is determined as
\[ \hat{x}(t, \cdot) = F_{k-1}[y(t, \cdot)] = \hat{x}(t_{k-1}, \cdot) + B_1[y(t, \cdot) - y(t_{k-1}, \cdot)]. \tag{14} \]

The conditions (8) and (12) are motivated by the device of piecewise function interpolation and associated advantages \cite{15}.

Filter $F^{(p-1)}$ of the form (4)–(5) with $\alpha_j$ and $B_j$ satisfying (8) and (12) is called the piecewise linear interpolation filter. The pair of signals $\{x(t_j, \cdot), y(t_j, \cdot)\}$ associated with time $t_k$ defined by (1) is called the interpolation pair.

IV. MAIN RESULTS

A. General device

In accordance with the scheme presented in Sections III-A and III-D above, an estimate of the reference signal $x(t, \cdot)$, for any $t \in T = [a, b]$, by the piecewise linear interpolation filter $F^{(p-1)}$, is given by
\[ \hat{x}(t, \cdot) = F^{(p-1)}[y(t, \cdot)] = \sum_{j=1}^{p-1} \delta_j F_j[y(t, \cdot)], \tag{15} \]
where, for each $j = 1, \ldots, p-1$, the sub-filter $F_j$ is given by (5), and is defined from the interpolation conditions (8) and (12).

Below, we show how to determine $F_j$ to satisfy the conditions (8) and (12).

B. Determination of piecewise linear interpolation filter

Let us denote
\[ z(t_j, t_{j+1}, \cdot) = x(t_{j+1}, \cdot) - \hat{x}(t_j, \cdot), \quad w(t_j, t_{j+1}, \cdot) = y(t_{j+1}, \cdot) - y(t_j, \cdot). \tag{16} \]
\[ w(t_j, t_{j+1}, \cdot) = [w_1(t_j, t_{j+1}, \cdot), \ldots, w_{m}(t_j, t_{j+1}, \cdot)]^T, \tag{17} \]
where $z^{(i)}(t_j, t_{j+1}, \cdot) \in L^2(\Omega, \mathbb{R})$ and $w^{(i)}(t_j, t_{j+1}, \cdot) \in L^2(\Omega, \mathbb{R})$ are random variables, for all $j = 1, \ldots, m$.

Then we can introduce the covariance matrix
\[ E_{z_{j}w_{j}} = \left\{ z^{(i)}(t_j, t_{j+1}, \cdot), w^{(k)}(t_j, t_{j+1}, \cdot) \right\}_{i,k=1}^{m,n}, \tag{18} \]
where
\[
\left\langle z^{(i)}(t_j, t_{j+1}), w^{(k)}(t_j, t_{j+1}) \right\rangle = \int_{\Omega} z^{(i)}(t_j, t_{j+1}, \omega) w^{(k)}(t_j, t_{j+1}, \omega) \, d\mu(\omega).
\]

Below, \(M^T\) is the Moor-Penrose generalized inverse of a matrix \(M\).

Now, we are in a position to establish the main results.

**Theorem 1:** Let
\[
K_x = \{ x(t, \cdot) \in L^2(\Omega, \mathbb{R}^m) \mid t \in T = [a, b] \}
\]
and
\[
K_y = \{ y(t, \cdot) \in L^2(\Omega, \mathbb{R}^n) \mid t \in T = [a, b] \}
\]
be sets of reference signals and observed signals, respectively.

Let \(t_j \in [a, b]\), for \(j = 1, \ldots, p\), be such that
\[
a = t_1 < \ldots < t_p = b.
\]

For \(t = t_1\), let \(\hat{x}(t_1)\) be a known estimate of \(x(t_1, \cdot)^9\). Then, for any \(t \in [a, b]\), the proposed piecewise linear interpolation filter \(\mathcal{F}^{(p-1)} : L^2(\Omega, \mathbb{R}^m) \rightarrow L^2(\Omega, \mathbb{R}^m)\) transforming any signal \(y(t, \cdot) \in L^2(\Omega, \mathbb{R}^m)\) to an estimate of \(x(t, \cdot)\), \(\hat{x}(t, \cdot)\), is given by
\[
\hat{x}(t, \cdot) = \mathcal{F}^{(p-1)}[y(t, \cdot)] = \sum_{j=1}^{p-1} \delta_j \mathcal{F}_j [y(t, \cdot)]
\]
where
\[
\mathcal{F}_j[y(t, \cdot)] = \hat{x}(t_j, \cdot) + B_j[y(t_j, \cdot) - y(t_j, \cdot)],
\]
\[(20)\]
and
\[
\hat{x}(t, \cdot) = \mathcal{F}_{j-1}[y(t, \cdot)] \quad \text{for} \quad j = 2, \ldots, p-1,
\]
\[(21)\]
and where \(I_n\) is the \(n \times n\) identity matrix and \(M_{B_j}\) is an \(m \times n\) arbitrary matrix.

**Proof:** The proof of Theorem 1 is given in the Appendix.

It is worthwhile to observe that, due to an arbitrary matrix \(M_{B_j}\) in (22), the filter \(\mathcal{F}^{(p-1)}\) is not unique. In particular, \(M_{B_j}\) can be chosen as the zero matrix \(\mathbb{O}\) similarly to the generic optimal linear [6] (which is also not unique by the same reason).

**C. Numerical realization of filter \(\mathcal{F}^{(p-1)}\) and associated algorithm**

1) **Numerical realization:** In practice, the set \(T = [a, b]\) (see Section II-A) is represented by a finite set \(\{\tau_1, \tau_2, \ldots, \tau_N\}\) where \(a = \tau_1 < \tau_2 < \ldots < \tau_N = b\).

For \(k = 1, \ldots, N\), the estimate of \(x(\tau_k, \cdot)\), \(\hat{x}(\tau_k, \cdot)\), and observed signal \(y(\tau_k, \cdot)\) are represented by \(m \times q\) and \(n \times q\) matrices
\[
\hat{X}^{(k)} = \hat{x}(\tau_k, \omega_1), \ldots, \hat{x}(\tau_k, \omega_q)
\]
and
\[
y^{(k)} = y(\tau_k, \omega_1), \ldots, y(\tau_k, \omega_q).
\]

The sequence of fixed time-points \(\{t_k\}_1^p \subset [a, b]\) introduced in (1) is such that
\[
t_1 = t_1 < \ldots < t_p = \tau_N,
\]
where
\[
t_1 = \tau_{n_0}, \quad t_2 = \tau_{n_0+n_1}, \quad \ldots, \quad t_p = \tau_{n_0+n_1+\ldots+n_{p-1}},
\]
and where \(n_0 = 1\) and \(n_1, \ldots, n_{p-1}\) are positive integers such that \(N = n_0 + n_1 + \ldots + n_{p-1}\).

For \(j = 1, \ldots, p\), signal \(y(t_j, \cdot)\) associated with \(t_j\) in (23) is represented by
\[
Y_j = [y(t_j, \omega_1), \ldots, y(t_j, \omega_N)].
\]

2) **Algorithm:** As it has been mentioned in Section III-D, it is supposed that, for \(t = t_1\), an estimate of \(X_1, \hat{x}_1\), is known and can be determined by the known methods. This is the initial condition of the proposed technique.

On the basis of the results obtained in Sections III-D and IV-B, the performance algorithm of the proposed filter consists of the following steps. For \(j = 1, \ldots, p\), we write \(N_j = n_0 + n_1 + \ldots + n_j-1\).

**Initial parameters:** \(Y^{(1)} = \ldots, Y^{(N)}, \{t_j\}_{j=1}^{p}\) (see (23)), \(\{E_{x_j}^{(p-1)}\}_{j=1}^{N}, \{E_{w_j}^{(p-1)}\}_{j=1}^{N}\) (see (16) and (18)), \(\hat{x}_1, n_0 = 1\) and \(M_{B_j} = \mathbb{O}\), for \(j = 1, \ldots, p-1\).

(Possible ways to get estimates of \(E_{x_j}^{(p-1)}\) and \(E_{w_j}^{(p-1)}\) are discussed below in Section IV-E.)

**Final parameters:** \(\hat{X}^{(2)}, \hat{X}^{(3)}, \ldots, \hat{X}^{(N)}\).

**Algorithm:**

- for \(j = 1 \rightarrow p\) do
  - begin
    - \(B_j = E_{x_j}^{(p-1)} E_{w_j}^{(p-1)};\)
    - for \(k = N_j + 1 \rightarrow N_j\) do
      - begin
        - \(\hat{X}^{(k)} = \hat{x}_j + B_j(Y^{(k)} - Y_j);\)
      - end
  - end

**D. Error analysis**

It is natural to expect that the error associated with the piecewise interpolating filter \(\mathcal{F}^{(p-1)}\) decreases when \(\max_{j=1, \ldots, p-1} \lambda_j\) decreases. Below, in Theorem 3, we justify that this observation is true. To this end, first, in the following Theorem 2, we establish an estimate of the error associated with the filter \(\mathcal{F}\).

Let us introduce the norm by
\[
||x(t, \cdot)||_2^2, \Omega = \frac{1}{b-a} \int_T ||x(t, \cdot)||_2^2\, dt.
\]
\[(24)\]

We also denote \(||x(t, \omega)||_2^2, \Omega = ||x(t, \omega)||_2^2, \Omega\).

Let us suppose that \(x(\cdot, \omega)\) and \(y(\cdot, \omega)\) are Lipschitz continuous signals, i.e. that there exist real non-negative constants \(\lambda_j\) and \(\gamma_j\), with \(j = 1, \ldots, p\), such that, for \(t \in [t_j, t_{j+1}]\),
\[
||x(t, \omega) - x(t_j, \omega)||_2^2, \Omega \leq \lambda_j \Delta t_j
\]
and
\[
||y(t, \omega) - y(t_{j+1}, \omega)||_2^2, \Omega \leq \gamma_j \Delta t_j
\]
\[(25)\]
\[(26)\]
where $s_j = |t_{j+1} - t_j|$.  

**Theorem 2:** Under the conditions (25) the error associated with the piecewise interpolation filter, \[ \|x(t, \omega) - F^{(p-1)}[y(t, \omega)]\|_2 \leq \Omega, \] is estimated as follows:

\[
\|x(t, \omega) - F^{(p-1)}[y(t, \omega)]\|_2^2 \leq \max_{j=1, \ldots, p} (\alpha_j + \gamma_j |B_j|) s_j \|x\|_2^2 + \|E_{z_2}y\|_2^2
\]

(27)

\[
\|E_{z_2}y\|_2^2 = \max_{j=1, \ldots, p} (\alpha_j + \gamma_j |B_j|) s_j \|x\|_2^2 + \|E_{z_2}y\|_2^2
\]

(28)

Proof: The proof of Theorem 2 is given in the Appendix. □

Further, to show that the error of the reference signal estimate tends to the zero, we need to assume that, for $t \in [t_1, t_2]$, the known estimate $\hat{x}(t, \omega)$ differs from $x(t, \omega)$ for the value of the order $\alpha_1$, i.e. that, for some constant $c_1 \geq 0$,  

\[
\|x(t, \omega) - \hat{x}(t, \omega)\|_2^2 \leq c_1 s_1, \quad \text{for } t \in [t_1, t_2].
\]

(30)

**Theorem 3:** Let the conditions (25) and (30) be true. Then the error associated with the piecewise interpolating filter $F$, \[ \|x(t, \omega) - F^{(p-1)}[y(t, \omega)]\|_2 \leq \Omega, \] decreases in the following sense:

\[
\|x(t, \omega) - F^{(p-1)}[y(t, \omega)]\|_2 \leq \max_{j=1, \ldots, p} (\alpha_j + \gamma_j |B_j|) s_j \|x\|_2^2 + \|E_{z_2}y\|_2^2
\]

(31)

\[
\|E_{z_2}y\|_2^2 \leq \max_{j=1, \ldots, p} (\alpha_j + \gamma_j |B_j|) s_j \|x\|_2^2 + \|E_{z_2}y\|_2^2
\]

(32)

Proof: The proof of Theorem 3 is given in the Appendix. □

**Remark 1:** We would like to emphasize that the statement of Theorem 3 is fulfilled only under assumptions (25) and (30). At the same time, the assumptions (25) and (30) are not restrictive from a practical point of view. The condition (25) is true for Lipschitz continuous signals $x$ and $y$, i.e. for very wide class of signals. The condition (30) is achieved by a choosing an appropriate known method (e.g. see [2]–[14], [24], [26]) to find the estimate $\hat{x}(t, \omega)$ used in the proposed filter $F^{(p-1)}$ (see (8) and Theorem 1).

E. Some remarks related to the assumptions of the method

As it has been mentioned in Section III-B, for $j = 1, \ldots, p$, matrices $E_{z_2}y$ and $E_{w_1}y$ in (22) are assumed to be known or can be estimated. Here, $p$ is chosen as a number of selected interpolation signal pairs (see Section III-D). We note that normally $p$ is much smaller than the number of input-output signals $x(t, \omega)$ and $y(t, \omega)$. Therefore, to estimate any signal $x(t, \omega)$ from an arbitrarily large set $K_{X}$, only a small number, $p$, of matrices $E_{z_2}y$ and $E_{w_1}y$ should be estimated (or known). This issue has also been discussed in Sections I-B1 and I-B4.

By the proposed method, $x(t, \omega)$ is estimated for $t \in [t_j, t_{j+1}]$. While $E_{w_1}y$ in (22) can be directly estimated from observed signals $y(t_{j+1}, \omega)$ and $y(t_j, \omega)$, an estimate of matrix $E_{z_2}y$, depends on the reference signal $x(t_{j+1}, \omega)$ (see (16) and (18)) which is unknown (because the estimate is considered for $t \in [t_j, t_{j+1}]$).

Some possible approaches to an estimation of matrix $E_{z_2}y$ could be as follows:

1. In the general case, when $x(t, \omega)$ and $y(t, \omega)$ are arbitrary signals as discussed in Section II-A above, matrix $E_{z_2}y$ can be estimated as proposed, for example, in [28], from samples of $z_j$ and $w_j$.

2. In the case of incomplete observations, the method proposed in [29], [30] can be used.

3. Let $E_{z_2}y$ be a matrix obtained from matrix $E_{z_2}y$ where the term $x(t_{j+1}, \omega)$ is replaced by $\hat{x}(t, \omega)$ with $t \in [t_j, t_j]$. Since $x(t, \omega)$ with $t \in [t_j, t_j]$ is known, matrix $E_{z_2}y$ can be considered as an estimate of $E_{z_2}y$.

4. In the important case of an additive noise, $E_{z_2}y$ can be represented in the explicit form. Indeed, if  

\[
y(t, \omega) = x(t, \omega) + \xi(t, \omega)
\]

where $\xi(t, \omega) \in L^2(\Omega, R^m)$ is a random noise, then  

\[
x(t_{j+1}, \omega) = y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega) - \hat{x}(t_j, \omega)
\]

and matrix $E_{z_2}y$ can be represented as follows:

\[
E_{z_2}y = E((y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega)) + E((y(t_{j+1}, \omega) - \hat{x}(t_j, \omega))
\]

(33)

We note that the RHS of (33) depends only on observed signals $y(t_{j+1}, \omega)$, $y(t_{j+1}, \omega)$, estimated signal $\hat{x}(t_j, \omega)$, and noise $\xi(t_{j+1}, \omega)$, not on the reference signal $x(t_{j+1}, \omega)$. In particular, in (33), the term $E((y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega))$ can be estimated as

\[
E((y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega))
\]

(34)

\[
\int_0^\infty E((y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega))^2) d\mu(\omega)
\]

It is motivated by the Holder’s inequality for integrals. The second term in (33), $E((y(t_{j+1}, \omega))$, can be estimated from the samples of $\hat{x}(t_{j+1}, \omega)$ and $y(t_{j+1}, \omega)$.

We also note that the first term in the RHS of (33), $E((y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega))$, is similar to the related covariance matrix in the Wiener filtering approach [6].

5. Other known ways to estimate $E((y(t_{j+1}, \omega) - \xi(t_{j+1}, \omega))$ can be found in [6], Section 5.3.

In general, an estimation of covariance matrices is a special research topic which is not a subject of this paper. The relevant references can be found, for example, in [6], [30].

V. CONCLUSION

The theory for a new approach to filtering arbitrarily large sets of stochastic signals $K_{X}$ and $K_{X}$ is provided. Distinctive features of the approach are as follows.

(i) The proposed filter $F^{(p-1)} : K_{Y} \rightarrow K_{X}$ is nonlinear and is presented in the form of a sum with $p-1$ terms where each term, $F_{j} : K_{Y} \rightarrow K_{X}$, is interpreted as a particular sub-filter. Here, $K_{Y}$ and $K_{X}$ are ‘small’ pieces of $K_{X}$ and $K_{X}$, respectively.

(ii) The prime idea is to exploit a priori information only on few reference signals, $p$, from the set $K_{X}$ that contains $N \gg p$ signals (or even an infinite number of signals) and determine $F_{j}$ separately, for each pieces $K_{Y}$ and $K_{X}$, so that the associated error is minimal. In other words, the filter $F^{(p-1)}$ is flexible to changes in the sets of observed and reference signals $K_{Y}$ and $K_{X}$, respectively.

(iii) Due to the specific way of determining $F_{j}$, the filter $F^{(p-1)}$ provides a smaller associated error than that for the processing of the whole set $K_{Y}$ by a filter which is not specifically adjusted to each particular piece $K_{Y}$. Moreover,
the error associated with our filter decreases when the number of its terms, \( F_1, \ldots, F_{p-1} \), increases.

(iv) While the proposed filter \( F^{(p-1)} \) processes arbitrarily large (and even infinite) signal sets, the filter is nevertheless fixed for all signals in the sets.

(v) The filter \( F^{(p-1)} \) is determined in terms of pseudo-inverse matrices so that the filter always exists.

(vi) The computational load associated with the filter \( F^{(p-1)} \) is less than that associated with other known filters applied to the processing of large signal sets.

**APPENDIX A**

**Proof of Theorem 1:** It follows from (8) and (12) that \( \alpha_j \), for \( j = 1, \ldots, p - 1 \), is given by

\[
\alpha_j = \tilde{x}(t, \omega) - B_j[y(t, \omega)].
\]

(34)

Further, for \( \alpha_j \) given by (34),

\[
\| \tilde{x}(t_{j+1}, \cdot) - \alpha_j - B_j[y(t_{j+1}, \cdot)] \|_{\Omega}^2
= \| \tilde{x}(t_{j+1}, \cdot) - B_j[w(t_{j+1}, \cdot)] \|_{\Omega}^2
\]

(35)

\[
= \text{tr}\{E_{z_{j+2}} - E_{z_{j+2}}B_j^* - B_jE_{w_{j+1}}^* \}
= \|E_{z_{j+2}}^1\|_2^2 - \|E_{z_{j+2}}E_{w_{j+1}}B_j^*\|_2^2
+ |B_j|\|E_{z_{j+2}}B_j^*\|_2^2 - |B_j|\|E_{z_{j+2}}E_{w_{j+1}}B_j^*\|_2^2
= \|E_{w_{j+1}}E_{w_{j+1}}E_{w_{j+1}}B_j^*\|_2^2 - \|E_{w_{j+1}}E_{w_{j+1}}B_j^*\|_2^2
\]

(36)

where \( \| \cdot \| \) is the Frobenius norm. The latter is true because

\[
E_{w_{j+1}}E_{w_{j+1}}E_{w_{j+1}}B_j^* = (E_{w_{j+1}}^2)\hat{\beta}_j.
\]

and

\[
E_{z_{j+2}}E_{z_{j+2}}E_{w_{j+1}}E_{w_{j+1}} = E_{z_{j+2}}E_{w_{j+1}}
\]

by Lemma 24 in [6]. Thus, the second expression in (12) is reduced to the problem

\[
\min_{B_j} \|E_{z_{j+2}}E_{w_{j+1}}B_j^*\|_2^2 - \|E_{w_{j+1}}E_{w_{j+1}}B_j^*\|_2^2.
\]

(37)

It is known (see, for example, [6], p. 304) that the solution of problem (37) is given by (22). The equation (20) follows from (6) and (34).

Theorem 1 is proven. \( \square \)

**Proof of Theorem 2:** For \( t \in [t_j, t_{j+1}] \) and \( F_j \) defined by (20)–(22),

\[
x(t, \omega) - F_j[y(t, \omega)]
= x(t, \omega) - F_j[y(t, \omega)]
= x(t, \omega) - \tilde{x}(t, \omega) + B_jy(t, \omega) - B_jy(t, \omega)
= \|x(t, \omega) - \tilde{x}(t, \omega)\| + \|z(t, t_{j+1}, \omega) - B_jw(t, t_{j+1}, \omega)\| + B_jy(t_{j+1}, \omega) - y(t, \omega).
\]

(38)

Then (38) and (38) imply

\[
\|x(t, \omega) - F_j[y(t, \omega)]\|_{\Omega}^2
\leq \|x(t, \omega) - \tilde{x}(t, \omega)\|_{\Omega}^2
+ \|z(t, t_{j+1}, \omega) - B_jw(t, t_{j+1}, \omega)\|_{\Omega}^2
+ \|B_jy(t_{j+1}, \omega) - y(t, \omega)\|_{\Omega}^2.
\]

(39)

where

\[
\|x(t, t_{j+1}, \omega) - B_jw(t, t_{j+1}, \omega)\|_{\Omega}^2
= \|x(t, t_{j+1}, \omega) - B_jw(t, t_{j+1}, \omega)\|_{\Omega}^2.
\]

(40)

It follows from (35) and (35) that for \( B_j \) given by (22),

\[
\|x(t, t_{j+1}, \omega) - B_jw(t, t_{j+1}, \omega)\|_{\Omega}^2
\]

(41)

\[
= \|E_{z_{j+2}}^1\|_2^2 - \|E_{z_{j+2}}E_{w_{j+1}}B_j^*\|_2^2.
\]

(42)

Then (19)–(22), (25) and (38)–(40) imply that for all \( t \in [a, b] \) and \( \omega \in \Omega \), (27) is true. \( \square \)

**Proof of Theorem 3:** The relation (24) implies that

\[
\|x(t, \omega) - F_j[y(t, \omega)]\|_{\Omega}^2
= \frac{1}{b-a} \int_{t_j}^{t_{j+1}} \|x(t, \omega) - F_j[y(t, \omega)]\|_{\Omega}^2 dt.
\]

(43)

where

\[
\|x(t, \omega) - F_j[y(t, \omega)]\|_{\Omega}^2
\]

(44)

\[
= \|x(t, \omega) - \tilde{x}(t, \omega) + B_j[y(t, \omega) - F_j[y(t, \omega)]]\|_{\Omega}^2
\]

(45)

\[
\leq \|x(t, \omega) - x(t, \omega)\|_{\Omega}^2 + \|x(t, \omega) - \tilde{x}(t, \omega)\|_{\Omega}^2 + \|F_j[y(t, \omega) - F_j[y(t, \omega)]]\|_{\Omega}^2.
\]

(46)

Thus consider an estimate of \( \|x(t_j, \omega) - \tilde{x}(t, \omega)\|_{\Omega}^2 \), for \( j = 1, \ldots, p - 1 \). To this end, let us denote \( \alpha = \max_{j=1,\ldots,p-1} t_j \).

For \( j = 1, \) i.e. for \( t \in [t_1, t_2] \),

\[
\|x(t, \omega) - F_1[y(t, \omega)]\|_{\Omega}^2
\]

(47)

\[
\leq \|x(t, \omega) - x(t_1, \omega)\|_{\Omega}^2 + \|x(t_1, \omega) - \tilde{x}(t_1, \omega)\|_{\Omega}^2 + \|F_1[y(t_1, \omega) - F_1[y(t_1, \omega)]]\|_{\Omega}^2
\]

(48)

\[
\leq \beta_1\Delta t + \|x(t_1, \omega) - \tilde{x}(t_1, \omega)\|_{\Omega}^2 + \|F_1[y(t_1, \omega) - \tilde{x}(t_1, \omega)]\|_{\Omega}^2
\]

(49)

where \( \beta_1 = \lambda_1 + \lambda_1 + \|F_1\|_{\gamma_1} \). In particular, the latter implies

\[
\|x(t_1, \omega) - \tilde{x}(t_1, \omega)\|_{\Omega}^2 + \|F_1[y(t_1, \omega) - \tilde{x}(t_1, \omega)]\|_{\Omega}^2 \leq \beta_1\Delta t
\]

(50)

For \( j = 2, \) i.e. for \( t \in [t_2, t_3] \),

\[
\|x(t, \omega) - F_2[y(t, \omega)]\|_{\Omega}^2
\]

(51)

\[
\leq \|x(t, \omega) - x(t_2, \omega)\|_{\Omega}^2 + \|x(t_2, \omega) - \tilde{x}(t_2, \omega)\|_{\Omega}^2 + \|F_2[y(t_2, \omega) - \tilde{x}(t_2, \omega)]\|_{\Omega}^2
\]

(52)

\[
\leq \beta_2\Delta t + \|x(t_2, \omega) - \tilde{x}(t_2, \omega)\|_{\Omega}^2 + \|F_2[y(t_2, \omega) - \tilde{x}(t_2, \omega)]\|_{\Omega}^2
\]

(53)

\[
\leq \beta_2\Delta t,
\]

(54)
where \( \beta_2 = \lambda_2 + \beta_1 + \|B_2\| \gamma_2 \). In particular, then it follows that
\[
\|x(t_j, \omega) - \tilde{x}(t_j, \omega)\|_{F_1}^2 = \|x(t_j, \omega) - F_2y(t_j, \omega)\|_{F_1}^2 \leq \beta_2 a t.
\]

On the basis of the above, let us assume that, for \( k = j - 1 \) with \( k = 2, \ldots, p - 1 \), i.e. for \( t \in [t_{k-1}, t_k) \),
\[
\|x(t_j, \omega) - \tilde{x}(t_j, \omega)\|_{F_1}^2 = \|x(t_j, \omega) - F_{k-1}y(t_j, \omega)\|_{F_1}^2 \leq \beta_{k-1} a t.
\]
where \( \beta_{k-1} \) is defined by analogy with \( \beta_2 \).

Then, for \( j = k \) with \( k = 2, \ldots, p - 1 \), i.e. for \( t \in [t_k, t_{k+1}] \),
\[
\|x(t_j, \omega) - F_ky(t_j, \omega)\|_{F_1}^2 \leq \|x(t_j, \omega) - F_{k-1}y(t_j, \omega)\|_{F_1}^2 + \|F_ky(t_j, \omega) - y(t_j, \omega)\|_{F_1}^2 \leq \lambda_k a t_k + \beta_{k-1} a t + \|B_k\| \gamma_2 a t_k \leq \beta_k a t,
\]
where \( \beta_k = \lambda_k + \beta_{k-1} + \|B_k\| \) for all \( t \in [a, b] \), and then it follows from (41)–(42) and (44) that for all \( t \in [a, b] \),
\[
\|x(t, \omega) - F[y(t, \omega)]\|_{F_2}^2 \leq \frac{1}{b - a} \sum_{j=1}^{p-1} \eta_j a t \leq \frac{1}{b - a} \sum_{j=1}^{p-1} \eta_j a t.
\]

Let us now choose \( c \in \mathbb{R} \) and \( d \in \mathbb{R} \) so that \( a = d - c \) and partition interval \( [c, d] \subset \mathbb{R} \) by points \( \tau_1, \ldots, \tau_p \) so that \( c = \tau_1 \) and \( \tau_j = \tau_1 + ja \) with \( j = 1, \ldots, p \). There exists an integrable (bounded) function \( \varphi : [c, d] \to \mathbb{R} \) such that, for \( \xi_j \in (\tau_j, \tau_{j+1}) \), \( \varphi(\xi_j) = 0 \). Then
\[
\lim_{\Delta t \to -\infty} \sum_{j=1}^{p-1} \eta_j a t = \lim_{\Delta t \to -\infty} \sum_{j=1}^{p-1} \varphi(\xi_j) a t = \int_c^d \varphi(\tau) d\tau < +\infty.
\]
Thus, \( \Delta t \sum_{j=1}^{p-1} \eta_j a t \to 0 \) as \( \Delta t \to 0 \).

As a result, (45)–(46) imply (31).
