Mutually Independent Hamiltonian Cycles of \( C_n \times C_n \)

Kai-Siou Wu and Justie Su-Tzu Juan*

Abstract—In a graph \( G \), a cycle is Hamiltonian cycle if it contains all vertices of \( G \). Two Hamiltonian cycles \( C_1 = \langle u_0, u_1, u_2, \ldots, u_{n-1}, u_0 \rangle \) and \( C_2 = \langle v_0, v_1, v_2, \ldots, v_{n-1}, v_0 \rangle \) in \( G \) are independent if \( u_i = v_i, u_i \neq v_i \) for all \( 1 \leq i < n - 1 \). In \( G \), a set of Hamiltonian cycles \( C = \{ C_1, C_2, \ldots, C_k \} \) is mutually independent if any two Hamiltonian cycles of \( C \) are independent. The mutually independent Hamiltonicity, \( \text{IHC}(G) = k \), of a graph \( G \) means there exists a maximum integer \( k \) such that there exists \( k \)-mutually independent Hamiltonian cycles start from any vertex of \( G \). In this paper we define \( C_n \) is a cycle with \( |V(C_n)| = n \).

Keywords—Hamiltonian, independent, cycle, Cartesian product, mutually independent Hamiltonicity.

I. INTRODUCTION

CYCLES are the fundamental class of network topologies for parallel and distributed computing, is suitable for designing simple algorithms with low communication costs [1]–[3]. For solving various algebraic problems, graph problems, and some parallel applications, there are many efficient parallel algorithms designed on cycles, such as those in imaging and signal processing, can be found in [1], [4]. If the network can be embed cycles, then we can use these algorithms as control/data flow structures for distributed computing in arbitrary networks so that the algorithms designed on cycles can be executed on the embedded cycles.

When designing a structure in interconnection network, we often transform this problem to graph for discussing and studying. Formally, A processor will be transformed to be a vertex and the connection between two processors will be transformed to be an edge. By this transformation, it can transform an interconnection network to a graph.

For definitions and notations, we follow [5]. A graph \( G = (V,E) \), \( V,E \) are finite set, where \( V \) is vertex set and \( E \) is edge set define as \( E \subseteq \{ (u,v) : (u,v) \) is an unordered pair of \( V \) \}. Two vertices \( u,v \) are adjacent if \( (u,v) \in E(G) \), \( u,v \in V(G) \). A path \( P[v_0, v_k] = \langle v_0, v_1, \ldots, v_k \rangle \) in \( G \), define as a sequence of adjacent vertices and for all \( 0 \leq i \leq j \leq k \), \( v_i \neq v_j \). Let \( P(i) = v_{i-1} \) be the \( i \)th vertex of path \( P \). A cycle \( C[v_0, v_k] = \langle v_0, v_1, \ldots, v_k \rangle \) in \( G \) is a sequence of adjacent vertices where \( v_0 = v_k, k \geq 3 \) and for all \( 0 \leq i \leq j \leq k \), \( v_i \neq v_j \) in \( G \). A cycle is Hamiltonian cycle if it contains all vertices of \( G \). Two Hamiltonian cycles \( C_1 = \langle u_0, u_1, u_2, \ldots, u_{n-1}, u_0 \rangle \) and \( C_2 = \langle v_0, v_1, v_2, \ldots, v_{n-1}, v_0 \rangle \) in \( G \) are independent if \( u_0 = v_0, u_i \neq v_i \) for all \( 1 \leq i \leq n \). A set of Hamiltonian cycles \( C = \{ C_1, C_2, \ldots, C_n \} \) start from the same vertex in \( G \) is mutually independent if any two Hamiltonian cycles of \( C \) are independent. The mutually independent Hamiltonicity, \( \text{IHC}(G) = k \), of a graph \( G \) means there exists a maximum integer \( k \) such that there exists \( k \)-mutually independent Hamiltonian cycles start from any vertex of \( G \). In this paper we define \( C_n \) is a cycle with \( |V(C_n)| = n \).

Broadcasting is an information dissemination process that involves one node in a network sending pieces of information to all other nodes in the network. Constructing a set of \( k \)-mutually independent Hamiltonian cycles enables us to efficiently broadcast a message formed of \( k \) pieces on a graph \( G \). The common starting vertex acts as the source to send the \( k \) pieces of the given message along the \( k \) parallel Hamiltonian cycles. This broadcasting can be done in \( O(n) \) time using an all-port model.

Given two graph \( G = (V_G, E_G), H = (V_H, E_H) \), the Cartesian product of \( G \) and \( H, G \times H \), is a graph which \( V = V_G \times V_H \), \( E = \{(p_1, q_1), (p_2, q_2) : (p_1, q_1), (p_2, q_2) \in E, (p_1, q_1) \in V_G, (p_2, q_2) \in V_H, (p_1 = p_2, q_1 \neq q_2) \} \). For a vertex \( u \in V(G) \), the neighbor of \( u \), \( N_G(u) \), is the set \( \{ v : (u,v) \in E(G) \} \). And \( \deg_G(u) = |N_G(u)| \) is called the degree of \( u \). In a graph \( G \), we use \( \Delta(G) \) and \( \delta(G) \) to denote the maximum degree and minimum degree of \( G \) such that \( \Delta(G) = \text{maximum degree}, \delta(G) = \text{minimum degree} \). When we consider IHC\((G)\), these mutually independent Hamiltonian cycles are start from any vertex of \( G \), then we can get a property as follows:

 Remark 1. For any graph \( G \), \( \text{IHC}(G) \leq \delta(G) \).

The mutually independent Hamiltonicity of a graph can be represented by a Latin square. A Latin square of order \( n \) is an \( n \times n \) matrix which each row and each column is an integer from 1 to \( n \), and in the same row or column, each number occur exactly once. If we remove any \( k \) rows of Latin square for \( 1 \leq k < n \), we can get a Latin rectangle.

Mutually independent Hamiltonian cycle problem is an important property for graph theory, there are many studies for this problem on different graph [6]–[12]. In 2005, Sun et al. study on the mutually independent Hamiltonicity of hypercube [13]. In 2007, Hsieh et al. study on fault-free mutually independent Hamiltonian cycles in hypercubes with faulty edges [14]. Lin et al. study on the pancake graphs and the star graphs in 2009 [15], Chang et al. study on \((n, k)\)-star graphs in 2009 [10]. In this paper, we study on mutually independent Hamiltonicity of \( C_n \times C_n \). And we prove that for \( n \geq 3 \), \( \text{IHC}(C_n \times C_n) = 4 \).

II. SYMBOL DEFINITION

Let $Z_n = \{0, 1, 2, \ldots, n-1\}$, $n \in N$ and let $V(C_n) = Z_n$. We refer to toroidal mesh graph [16] and define graph $C_n \times C_n$, $n \geq 3$ as follows: The vertex set $V(C_n \times C_n) = \{(x, y) : x, y \in Z_n\}$; the edge set $E(C_n \times C_n) = \{\{u_1, u_2\}, \{v_1, v_2\} \in V(C_n \times C_n) \text{ and } u_1 = v_1, \text{ or } u_2 = v_2, \text{ or } v_1 - v_2 \in \{1, n-1\}\}$. We use this symbol definition to construct $C_5 \times C_5$ as Fig. 1. A graph $G$ is a $k$-regular graph if for all $x \in V(G)$, $deg_G(x) = k$. And a graph is vertex transitive if every vertex can be mapped to any other vertex by some automorphism [2].

By definition, $C_n \times C_n$ is a 4-regular graph with $n^2$ vertices and it is vertex transitive.

In $C_n \times C_n$, we use $C^i$ to denote the $i$th subgraph of $C_n \times C_n$ for $i \in Z_n$; the vertex set $V(C^i) = \{(i, v) : v \in Z_n\}$; and the edge set $E(C^i) = \{(i, v_1), (i, v_2) \in V(C^i) \text{ and } v_1 = v_2 \in \{1, n-1\}\}$ is a path of $C^i$ which is from $(i, x)$ to $(i, y)$ and the index of vertices are increased. And $P_{i,x,y}$ is a path of $C_n \times C_n$ which is from $(i, x)$ to $(i, y)$ and the index of vertices are decreased. Note that the operation $+$ or $-$ should be calculate on $Z_n$. In a cycle $C$; we use $C(t) = x$ for $1 \leq t \leq |C|$ to denote the $t$th vertex of $C$ from the start vertex.

III. MAIN RESULT

We study on mutually independent Hamiltonicity of $C_n \times C_n$ in this section. First, we prove some lemmas and use them to show that $IHC(C_n \times C_n) = 4$. We show results as follows.

Fig. 2. A Latin square order $n$, which subtract 1 from each element.

Fig. 3. A matrix of $u = a = v = 0, b \in Z_n, b \neq 0$.

**Lemma 1.** For any odd positive integer $n \geq 3$, $IHC(C_n) = 2$.

**Proof.** Let $V(C_n) = Z_n$, it is easy to see that there exists two Hamiltonian cycles $H_1, H_2$ as follow:

- $H_1 : (0, 1, 2, \ldots, n-1), H_2 : (0, n-1, n-2, \ldots, 1)$.

So, for all $1 \leq i \leq n$, $H_1(i) = i - 1; H_2(1) = 0$ and for all $2 \leq j \leq n$, $H_2(j) = n - j + 1$. Thus, for all $2 \leq k \leq n$, $H_1(k) + H_2(k) = n$. Since $n$ is odd, $H_1(k) \neq H_2(k)$. Then there exists two independent Hamiltonian cycles start from vertex 0. Since cycle is vertex transitive, there exists two independent Hamiltonian cycles start from any vertex of $C_n$. Hence, $IHC(C_n) \geq 2$. By Remark 1, we can know that $IHC(C_n) = 2$. \hfill \Box

It is not too difficult to see that the following lemma is true.

**Lemma 2.** For any graph $G$, if there exists two $P_1, P_2$ and a subgraph $C_n \subseteq G$ with $V(C_n) = \{x_0, x_1, \ldots, x_{n-1}\}$. For all $1 \leq i \leq 2, 0 \leq j \leq n - 1, P_{i,t}(t, j + 1) \in V(C_n)$. Let $P_{i,1} = (t_1 + j) = x_0, P_{i,2} = (t_2 + j) = x_1$ for $0 \leq j \leq n - 1$. If $a = mod n, t_1 - t_2 = b \mod n$ for some, $a, b \in Z_n$ and $a \neq b$, then these 2 paths are not at the same vertex of $C_n$ in the same time.

Fig. 3 is an illustration of Lemma 2.

**Theorem 1.** For $n \geq 3$ and $n$ is odd, $IHC(C_n \times C_n) = 4$.

**Proof.** Since $C_n \times C_n$ is 4-regular graph, $IHC(C_n \times C_n) \leq 4$ by Remark 1. Next, we will show that $IHC(C_n \times C_n) \geq 4$ by constructing 4-mutually independent Hamiltonian cycles from any vertex of $C_n \times C_n$. Without loss of generality, we may assume that start vertex $e = (0, 0)$ because $C_n \times C_n$ is vertex transitive. We construct 4 mutually independent Hamiltonian cycles $H_1, H_2, H_3$ and $H_4$ start from $e$ as follows:

- $H_1 = (0, 0), P_{0,0,0,0,1,1}, (0, n - 1), (1, n - 1), (1, n - 1), P_{1,1,1,1,1,1}, (1, n - 1), (2, n - 2), P_{2,2,2,2,2,2}, (2, n - 3), \ldots, (n - 1, 1), P_{n-1,n-1,n-1,n-1,n-1,n-1}$.

- $H_2 = (0, 0), (1, 1), P_{0,0,0,1,1,1}, (0, n - 1), (1, n - 1), P_{1,1,1,1,1,1}, (1, n - 1), (2, n - 2), P_{2,2,2,2,2,2}, (2, n - 3), \ldots, (n - 1, 1), P_{n-1,n-1,n-1,n-1,n-1,n-1}$.

- $H_3 = (0, 0), (1, 1), P_{0,0,0,1,1,1}, (0, n - 1), (1, n - 1), P_{1,1,1,1,1,1}, (1, n - 1), (2, n - 2), P_{2,2,2,2,2,2}, (2, n - 3), \ldots, (n - 1, 1), P_{n-1,n-1,n-1,n-1,n-1,n-1}$.
(n - 1), (n - 1), (0, n - 1), P_{0,n-1,0,-}, (0, 0),
H_3 = \langle (0, 0), (n - 1, 0), P_{n-1,0,n-1,-}, (n - 1, n - 1),
(n - 2, n - 1), P_{n-2,1,n-1,-}, (n - 2, n - 2), (n - 3, n - 2),
P_{n-3,2,n-2,-}, (n - 3, n - 3), ..., (0, 1), P_{0,1,0,+}, (0, 0)\rangle.
H_4 = \langle (0, 0), P_{0,1,0,-}, (0, 1), (n - 1, 1), P_{n-1,1,-},
(n - 2, 2), P_{n-2,2,-}, (n - 2, 3), ..., (1, n - 1),
P_{1,n-1,-}, (1, 0), (0, 0)\rangle.

We represent H_1, H_2, H_3 and H_4 as graph in Fig. 4.
According to vertices H_i(t), for 2 ≤ t ≤ n^2, i ∈ \{1, 2, 3, 4\} belong to different subgraph C_j^i, for j ∈ \mathbb{Z}_n or not, we have following cases:

**Case 1:** 2 ≤ t ≤ n and n(n - 1) + 2 ≤ t ≤ n^2.
For any 2 ≤ t_1 ≤ n and n(n - 1) + 2 ≤
t_2 ≤ n^2. By the construction of H_1, H_2, H_3 and H_4,
we can know that H_1(t_1), H_2(t_1) ∈ V(C^{(0)}); H_2(t_1) ∈
V(C^{(1)}); H_3(t_1) ∈ V(C^{(n-1)}) and H_3(t_2) ∈ V(C^{(1)});
H_4(t_2), H_3(t_2) ∈ V(C^{(0)})\text{; } H_4(t_2) ∈ V(C^{(n-1)}). By Lemma
1, H_1(t_1) \neq H_2(t_1) and H_2(t_2) \neq H_3(t_2). In the same time,
H_2(t_1), H_3(t_1); H_2(t_2), H_3(t_2) are in different subgraph, so
H_i(t) \neq H_j(t), for i, j ∈ \{1, 2, 3, 4\}, i \neq j, for 2 ≤ t ≤ n
or n(n - 1) + 2 ≤ t ≤ n^2. That is, H_1, H_2, H_3 and H_4 are
mutually independent for this case.

**Case 2:** t = in + 1, for all 1 ≤ i ≤ n - 1.

From the construction of 4 Hamiltonian cycles, we can know
that for all 1 ≤ i ≤ n - 1, t = in + 1, H_1(t) = (i, n - i); H_2(t) = (i, i); H_3(t) = (n - i, n - i); H_4(t) = (n - i, i).
Since n is odd, n - i \neq i. It means that when t = in + 1, for
1 ≤ i ≤ n - 1 H_1(t), H_2(t), H_3(t), H_4(t) are distinct.

**Case 3:** in + 2 ≤ t ≤ in + n, for all 1 ≤ i ≤ n - 2 and
i \neq (n - 1)/2.
For all 1 ≤ i ≤ n - 2 and i \neq (n - 1)/2 and in + 2 ≤
t ≤ in + n, H_1(t) ∈ V(C^i), H_2(t) ∈ V(C^{i+1}), H_3(t) ∈
V(C^{n-i-1}), and H_4(t) ∈ V(C^{n-i}). It is trivial that i \neq i +
1, n - i + 1 \neq n - i. Since i \neq (n - 1)/2, then i \neq n - i
- 1; i + 1 \neq n - i. Besides, i \neq n - i and i + 1 \neq n - i - 1, for n
is odd. Hence, H_1, H_2, H_3 and H_4 are mutually independent
in this range.

**Case 4:** in + 2 ≤ t ≤ in + n, when i = (n - 1)/2.
When t = in + 2, H_1(t - 1) = H_3(t); H_4(t - 1) = H_2(t),
and for all in + 2 ≤ t ≤ in + n, i = (n - 1)/2, H_1(t), H_3(t) ∈
V(C^i); H_2(t), H_4(t) ∈ V(C^{i+1}). In this interval, (H_1(in + 1),
H_1(in + 2), ..., H_1(in + n)) = (H_2(in + 2), H_2(in + 3), ..., H_2(in + n + 1)) = H_3(t)
= P_{i+1,i+1} and (H_2(in + 2), H_2(in + 3), ..., H_2(in + n + 1)) = H_3(t)
= P_{i+1,i+1}.

From the above discussion H_1, H_3 and H_2, H_4 are independent.
Besides, H_1, H_3 and H_2, H_4 are in different subgraphs.
Thus, H_1, H_2, H_3 and H_4 are mutually independent in this
range.

From the above 4 cases, we can know that H_1, H_2, H_3
and H_4 start from e are mutually independent. Hence,
IHC(C_n × C_n) ≥ 4 and it implies IHC(C_n × C_n) = 4 for
odd integer n ≥ 3. □

We construct 4-mutually independent Hamiltonian cycles
of C_5 × C_5 in Fig. 5, 6, 7, 8 as an example of Theorem 1.
Next, we discuss the number of IHC(C_n × C_n) for n is an
even positive integer with n ≥ 4.

**Theorem 2.** For n ≥ 4 and n is even, IHC(C_n × C_n) = 4.
Fig. 6. Hamiltonian cycles $H_2$ in $C_5 \times C_5$.

Fig. 7. Hamiltonian cycles $H_3$ in $C_5 \times C_5$.

Fig. 8. Hamiltonian cycles $H_4$ in $C_5 \times C_5$.

Proof. Since $C_n \times C_n$ is 4-regular graph, $IHC(C_n \times C_n) \leq 4$ by Remark 1. Without loss of generality, we may assume that start vertex $e = (0, 0)$ because $C_n \times C_n$ is vertex transitive. For $n = 4$, we construct 4-mutually independent Hamiltonian cycles $H_1, H_2, H_3$ and $H_4$ start from $e$ as Fig. 9. For $n \geq 6$, we construct 4-mutually independent Hamiltonian cycles $H_1, H_2, H_3$ and $H_4$ start from $e$ as follows:

$$H_1 = ((0, 0), (0, 1), (1, 1), P_{1,1,2}, (1, 2), (2, 2), P_{2,2,3}, (2, 3), (3, 3), P_{3,3,4}, (3, 4), ..., (n - 2, n - 2), P_{n-2,n-2,n-1}, (n - 1, n - 1), (0, n - 1), (n, n - 1), (0, 0), (0, 0)).$$

$$H_2 = ((0, 0), (0, 1), P_{0,0,1}, (1, 1), (2, 2), P_{2,2,3}, (2, 3), (3, 3), ..., (0, n - 1), P_{0,n-1,0}, (0, 0)).$$

$$H_3 = ((0, 0), (0, 1), P_{n-1,0,n-2}, (1, 1), (2, 2), P_{2,2,3}, (2, 3), (3, 3), P_{3,3,4}, ..., (n - 2, n - 2), P_{n-2,n-2,n-1}, (n - 1, n - 1), (0, n - 1), (0, 0)).$$

$$H_4 = ((0, 0), P_{0,0,1}, (0, 1), (1, 1), P_{1,1,2}, (1, 2), (2, 2), P_{2,2,3}, (2, 3), (3, 3), P_{3,3,4}, ..., (n - 2, n - 2), P_{n-2,n-2,n-1}, (n - 1, n - 1), (0, n - 1), (0, 0)).$$

We represent $H_1, H_2, H_3$ and $H_4$ as graph in Fig. 10. According to $H_2(t), 2 \leq t \leq n^2$, $1 \in \{1, 2, 3, 4\}$ belong to the same subgraph $C_1$ for some $j \in Z_n$ or not, we have following cases:

**Case 1:** $t = 2, n^2 - 1, n^2$.

For $t = 2$, $H_1(2) = (0, 1), H_2(2) = (1, 0), H_3(2) = (n - 1, 0), H_4(2) = (0, n - 1)$. And for $t = n^2 - 1, H_1(n^2 - 1) = (n - 1, 1), H_2(n^2 - 1) = (0, 2), H_3(n^2 - 1) = (n - 1, n - 1), H_4(n^2 - 1) = (1, 1)$. For $t = n^2$, $H_1(n^2) = (n - 1, 0), H_2(n^2) = (0, 1), H_3(n^2) = (0, n - 1), H_4(n^2) = (1, 0)$. Hence, $H_1, H_2, H_3$ and $H_4$ are mutually independent in this case.

**Case 2:** $i - 1)n + 3 \leq t \leq in + 2$, for all $1 \leq i \leq n - 2$.

For any $1 \leq i \leq n - 2$, for all $i - 1)n + 3 \leq t \leq in + 2$, $H_1(t), H_2(t) \in V(C^i)$. Two paths $H_1$ and $H_2$ go the same way in $C_i$. Let $H_1((i - 1)n + 3) = (i, v), H_2((i - 1)n + 3) = (i, v)$. By the construction of $H_1$ and $H_2$, we can know that $v \equiv (n - 1) \mod n$. By Lemma 2 and $H_1((i + n) \in V(C^i))$, $H_2((n + 2) \in V(C^i+1)$ for any $1 \leq i \leq n - 2$. $H_1$ and $H_2$ are independent for $(i - 1)n + 3 \leq t \leq in + 2$, $1 \leq i \leq n - 2$.

Then, we have the following subcases:

**Case 2.1:** $3 \leq t \leq n$.

$H_1(t), H_2(t) \in C^i, H_3(t) \in C^{n-1}$ and $H_4(t) \in C^0$, for
\[ \begin{align*}
\text{Case} & \quad 1 & 2 & 2 & 2 \\
H_1 & = P_{1,1.2, -} P_{2,2.3, -} P_{3,3.4, -} \\
& \quad (0,1) \quad P_{2,1.2, -} \quad P_{3,2.3, -} \\
H_2 & = P_{0,0.1, -} P_{1,1.2, -} P_{2,2.3, -} \\
& \quad P_{0,n,2,1, -} P_{1,2,3, -} P_{3,3.4, -} \\
H_3 & = P_{0,1,1.2, -} P_{1,0,1, -} P_{2,2,1, +} P_{3,4,0,1, -} \\
& \quad P_{0,n,1,2, -} P_{1,3,0,1, +} P_{2,5,1,0, +} P_{3,1,0,1, -} \\
H_4 & = \ldots \\
\end{align*} \]

Fig. 10. The construction of 4 Hamiltonian cycles start at e

\[ 3 \leq t \leq n. \text{ Since } H_1 \text{ and } H_2 \text{ are independent and } H_3, H_4 \text{ are in different subgraph with } H_1 \text{ and } H_2, \text{ then } H_1, H_2, H_3 \text{ and } H_4 \text{ are mutually independent in this subcase.} \]

**Case 2.2:** \( n + 1 \leq t \leq 2n - 2 \).

\[ H_1(t) \in V(C^1) \text{ for } t \in \{n + 1, n + 2\} \text{ and } H_1(t) \in V(C^2) \text{ for } n + 3 \leq t \leq 2n - 2, \]

\[ H_2(t) \in V(C^1) \text{ for } t = n + 1, \text{ and } \]

\[ H_3(t) \in V(C^3) \text{ for } n + 2 \leq t \leq 2n - 2, \]

\[ H_4(t) \in V(C^{0,-1}) \text{ for } n + 3 < t < 2n - 3, \]

Since \( H_1 \) and \( H_2 \) are independent and \( H_3, H_4 \) are in different subgraph with \( H_1 \) and \( H_2 \), then \( H_1, H_2, H_3 \) and \( H_4 \) are mutually independent for \( n + 1 \leq t \leq 2n - 2 \).

**Case 2.3:** \( 2n - 1 \leq t \leq 2n + 2 \).

\[ \text{For } 2n - 2 \leq t \leq 2n + 1, H_1(t) \text{ and } H_2(t) \in V(C^2), \]

\[ H_3(t) \in V(C^{0,-1}) \text{ and } H_4(t) \in V(C^{0,-1}) \text{ for } t \in \{2n - 1, 2n\} \text{ and } H_1(t) \in V(C^{0,-1}) \text{ for } t \in \{2n + 1, 2n + 2\}. \]

Since \( H_1 \) and \( H_2 \) are independent and \( H_3, H_4 \) are in different subgraph with \( H_1 \) and \( H_2 \), then \( H_1, H_2, H_3 \) and \( H_4 \) are mutually independent in this subcase.

**Case 2.4:** \( i \leq i + 3 \leq t \leq i + 2n + 2 \).

This case is similar to the previous one.

**Case 2.4.1:** \( i \leq i + 3 \leq t \leq i + 2n + 2 \).

When \( t \) is in this interval, \( H_1(t), H_2(t) \in V(C^0), H_3(t) \in V(C^{0,-1}), H_4(t) \in V(C^{0,-1}) \) since \( i \leq i \leq i + 2n + 2 \) and \( H_1, H_2, H_3, H_4 \) are independent in this subcase.

**Case 2.4.2:** \( i \leq i + 3 \leq t \leq i + 2n + 2 \).
Fig. 11. Hamiltonian cycles $H_1$ in $C_6 \times C_6$.

$4 + 2j = n$. Since $n \geq 6$ and $j \geq \lceil n/4 \rceil - 2$, a contradiction. So, $n - 2 - 2j \neq (n - 6 - 4j) \pmod n$. In the same way, we can know that $n - 3 - 2j \neq (n - 7 - 4j) \pmod n$. Hence, $H_1, H_2$ are independent, that implies $H_1, H_2, H_3$ and $H_4$ are mutually independent in this subcase.

Case 3.2: \((n - 1)n + 2 \leq t \leq n^2 - 2\).

In this case, $H_1(t) \in V(C^6) \cup V(C^{n-2})$, $H_2(t) \in V(C^6)$, $H_3(t) \in V(C^{n-2})$ and $H_4(t) \in V(C^6)$. $H_3, H_4$ are in different subgraph with $H_1, H_2$, we only need to consider the vertices of $H_1$ and $H_2$ in this subcase. Let $x = (n - 1)n + 2$, $y = \lceil n/4 \rceil - 1$, $0 \leq j \leq y$. By the construction of $H_1$ and $H_2$, we get:

The set $\{H_1(x) \in V(C^6) : x \leq z \leq n^2 - 2\} = \{H_1(x + 4j) = (0, 2(y - j) + 3), H_1(x + 1 + 4j) = (0, 2(y - j) + 2) : \text{for all } 0 \leq j \leq y\}$. The set $\{H_2(x) \in V(C^6) : x \leq z \leq n^2 - 2\} = \{H_2(x + kj) = (0, n - 1 - k) : 0 \leq k \leq n + 3\}$. Since $2(y - j) + 3 \neq n - 1 + 4j, 2(y - j) + 2 \neq n - 1 - 4j + 1$, then $H_1$ and $H_2$ are independent. Thus, $H_1, H_2, H_3$ and $H_4$ are mutually independent in this subcase.

From the above 3 cases, we can know that $H_1, H_2, H_3$ and $H_4$ start from $e$ are mutually independent and $IHC(C_n \times C_n) \geq 4$. Hence, $IHC(C_n \times C_n) = 4$ can be concluded.

We construct 4-mutually independent Hamiltonian cycles $C_6 \times C_6$ in Fig. 11, 12, 13, 14 as an example of Theorem 2.

IV. Conclusion

In this paper, we discuss the mutually independent Hamiltonian cycles of $C_n \times C_n$, for $n \geq 3$ and get the optimal result on it. Note that a Hamilton cycle in any graph $G$ is a cycle $C_n$ with $n = |V(G)|$. So, if two graphs $G_1$ and $G_2$ are Hamiltonian with $|V(G_1)| = |V(G_2)| = n \geq 3$, then graph $C_n \times C_n$ will be a spanning subgraph of $G_1 \times G_2$. Hence, we have the following corollary.

**Corollary 1.** For any graphs $G_1, G_2$, if $G_1$ and $G_2$ are Hamiltonian and $|V(G_1)| = |V(G_2)| \geq 3$, then

Fig. 12. Hamiltonian cycles $H_2$ in $C_6 \times C_6$.

Fig. 13. Hamiltonian cycles $H_3$ in $C_6 \times C_6$.

Fig. 14. Hamiltonian cycles $H_4$ in $C_6 \times C_6$. 
IHC\((G_1 \times G_2) \geq 4\).

In the future, discuss in the mutually independent Hamiltonian cycles of \(C_m \times C_n\), for \(m, n \geq 3\) and \(m \neq n\) is an interesting question. Furthermore, we can discuss IHC\((G)\) for \(G = C_n^k = C_n \times C_n \times \ldots \times C_n\), or more general graph \(C_{n_1} \times C_{n_2} \times \ldots \times C_{n_k}\), for any positive integer \(n_1 \geq n_2 \geq \ldots \geq n_k \geq 3\).
