Analyzing and Comparing the Hot-spot Thermal Models of HV/LV Prefabricated and Outdoor Oil-Immersed Power Transformers

Ali Mamizadeh, Ires Iskender

Abstract—The most important parameter in transformers life expectancy is the hot-spot temperature level which accelerates the rate of aging of the insulation. The aim of this paper is to present thermal models for transformers loaded at prefabricated MV/LV transformer substations and outdoor situations. The hot-spot temperature of transformers is studied using their top-oil temperature rise models. The thermal models proposed for hot-spot and top-oil temperatures of different operating situations are compared. Since the thermal transfer is different for indoor and outdoor transformers considering their operating conditions, their hot-spot thermal models differ from each other. The proposed thermal models are verified by the results obtained from the experiments carried out on a typical 1600 kVA, 30/0.4 kV, ONAN transformer for both indoor and outdoor situations.

Keywords—Hot-spot Temperature, Dynamic Thermal Model, MV/LV Prefabricated, Oil Immersed Transformers

I. INTRODUCTION

AGING of equipment is predominantly due to a thermal breakdown of its insulating medium [1, 8]. The insulation aging phenomenon has been well documented as a thermal deterioration process in the literature. The most important parameter that should be taken under control is the operating temperature of transformer. For this purpose, deriving and study of the thermal model of a transformer is getting more importance. The thermal model of a transformer is also important when it is aimed to manage the load profile of a power transformer [2, 3, 6] and to program its loading. In power systems the usage of indoor transformer station is preferred due to several reasons such as safety and environmental problems. The variation of the temperature is described by an exponential equation based on the time constant of the transformer top-oil temperature. The temperature of the winding is not uniform and the real limiting factor is actually the hottest section of the winding commonly called winding hot-spot. This hot-spot area is located somewhere toward the top of the transformer, and not accessible for direct measurement with usual methods. The hot-spot temperature in a transformer winding is the result of summing the ambient temperature, the top-oil temperature rise, and the hot-spot temperature rise over the top-oil temperature. It is assumed that during a transient period, the hot-spot temperature rise with respect the top-oil temperature varies instantaneously with transformer loading, more rapidly than the top oil temperature. In the proposed hot-spot and top-oil thermal models which are based on the thermal-electrical analogy, the ambient temperature and its variation in times have been considered. In the proposed models, the thermal resistance of air ventilation of the cabinet, the thermal resistances and thermal capacitances of different parts of the cabinet (ceiling, walls, door) are considered [2]. The method proposed for calculating thermal capacitance of top-oil temperature rise of oil immersed transformers is in accord with the IEEE Std C57.91-1995 Annex G and is suitable for both aluminum and copper windings [9].

II. FUNDAMENTAL THEORY OF THERMAL–ELECTRICAL ANALOGY

The analogy between thermal and electric process is briefly given below to analyze the thermal behavior of the inside of the power transformer [2, 6, 9, 10]. A thermal process can be defined by the energy balance given in Eqn. 1.

\[
q = C_{th} \frac{d\theta}{dt} + \frac{\theta - \theta_{amb}}{R_{th}}
\]

Eqn. 2 is similar to Eqn. 1 corresponding to a simple electric RC circuit.

\[
i = C_{el} \frac{dv}{dt} + \frac{v}{R_{el}}
\]

The analogy between thermal and electrical process is shown in Fig. 1-a and b, respectively.
III. THERMAL MODELING

Power losses are converted into heat in a transformer. The losses are composed of no-load losses and load losses. The no-load losses are comprised of eddy-current and hysteresis losses of the core. The load losses are comprised of resistive losses (losses of windings, joint points and connectors), winding eddy current losses and the stray losses.

The heat generated in a transformer transfers (from heat source to oil, from oil to surface and from surface to external environment) by three different heat transfer mechanisms - convection, conduction and radiation. The thermal model is based on the energy balances for the windings, oil, core and tank, cooling equipment and cooling environment.

A. Top oil thermal modeling of outdoor situation

The thermal equivalent circuit of an ONAN/OFAF (oil-natural air-natural/oil-forced air-forced) power transformer includes thermal resistance, thermal capacitor and thermal current source. The extended top-oil thermal circuit and model of a power transformer is presented in [2].

For a power transformer, $q_{str}$, $q_{fe}$, $q_{pri}$, $q_{sec}$ are the heats generated by the stray losses, the core losses, the primary winding losses and the secondary winding losses, respectively. $C_{om}$, $C_{fe}$, $C_{pri}$, $C_{sec}$ are the thermal capacitances of the tank including the other metal components, the core, the primary winding conductor, and the secondary winding conductor, respectively. $R_{om-o}$, $R_{fe-o}$, $R_{w-o}$, $R_{th-oil-air}$ are the thermal resistances of the tank including the other metal components to oil, core to oil, the windings to oil, and the oil to air, respectively. $\theta_{oil}$ and $\theta_{amb}$ are the top-oil and the ambient temperatures, respectively [2, 9].

The load losses can be considered as sum of resistive and stray losses:

$$q_l = q_{pri} + q_{sec} + q_s$$

(3)

The thermal resistances $R_{om-o}$, $R_{fe-o}$, and $R_{w-o}$ which are in range of $5 \times 10^{-5}$ K/W are very low with respect to $R_{th-oil-air}$ [2, 6]. Therefore, the equivalent thermal model given in [2] can be simplified as Fig. 2.

The thermal capacitance ($C_{th-oil}$) of power transformer top-oil equivalent circuit can be written as [2]:

$$C_{th-oil} = C_{om} + C_{fe} + C_{pri} + C_{sec} + C_{oil}$$

(4)

The top-oil thermal model introduced by IEEE is shown by a first order differential equation as given below [1].

$$\tau_{to} \frac{d\theta_{tor}}{dt} = -\theta_{tor} + \theta_i$$

(5)

The top-oil temperature rise is obtained from Eqn. 5 as:

$$\theta_{tor} = (\theta_i - \theta_t)(1 - e^{-\frac{t}{\tau_{to}}}) + \theta_t$$

(6)

Eqn. 7 gives the top-oil thermal model suggested by IEEE [1].

$$\left[ \frac{K^2 \beta + 1}{\beta + 1} \right] \Delta \theta_{tor} = \tau_{to} \frac{d\Delta \theta_{tor}}{dt} + \Delta \theta_{tor}$$

(7)

The top-oil time constant at rated power (kVA) is obtained from Eqn. 8 [1, 11].

$$\tau_{to} = C_{th-oil} R_{th-oil-air}$$

(8)

The thermal capacitance of power transformer top-oil is obtained from Eqn. 9 [9].

$$C_{th-oil} = 0.1323 \text{ (weight of core in kilograms)} + 0.3162 \text{ (weight of aluminum conductors in kg)} + 0.3513 \text{ (liters of oil)}$$

(9)

The thermal resistance $R_{th-oil-air}$ is given by Eqn. 10 [6, 9].
\[ R_{\text{th-oil-air}} = \frac{\Delta \theta_{\text{oil}}}{q_{\text{hot}}} \]  

(10)

The transformer top-oil thermal model given in Fig. 2 is derived from the thermal-analogy and heat transfer theory. The mathematical model corresponding to Fig. 2 is as;

\[ q_{fe} + q_{i} = C_{\text{th-oil}} \frac{d \theta_{\text{oil}}}{dt} + \left( \frac{\theta_{\text{oil}} - \theta_{\text{amb}}}{R_{\text{th-oil-air}}} \right) \]  

(11)

B. Top oil thermal modeling of indoor Situation

Due to limited ventilation in indoor operation the thermal resistance and thermal capacitance of indoor and outdoor transformers are different. The heat transfer between bodies is as follows:

1. From winding to oil
2. From oil to surrounding air
3. Air inside the room is cooled by natural ventilation and convection heat transfer from the air to room parts (door, walls and ceiling).
4. The heat transfer through the door

The extended model and analogues circuit is presented in [2]. According to presented model, the first cooling component which is dominant is represented by thermal resistance of room to ambient, \( R_{\text{room-amb}} \). The initial form of this thermal resistance is derived from the Hoppner formula [2, 5]. This formula (Eqn. 12) gives the relationship among \( P \) (power transferred by natural ventilation), \( \alpha \) (hydraulics resistance of air circulation), \( H \) (cabinet height), and \( \theta_{\text{ax}} \) (temperature difference between inlet and outlet holes air).

\[ S = \sqrt{\frac{13.2P^2R_{\text{hyd}}}{\theta_{\text{ax}}^3H}} \]  

(12)

From Eqn. 12, \( P \) is derived in terms of the other parameters as given in Eqn. 13.

\[ P = \sqrt{\frac{H}{13.2R_{\text{hyd}}}} S \theta_{\text{ax}}^{1.5} \]  

(13)

For the given ventilation hole area, cabinet height, and hydraulics resistance of air circulation the expression under the root sign is constant and the Eqn. 13 can be simplified as Eqn. 14.

\[ P = c_{\text{con}} \theta_{\text{ax}}^{1.5} \]  

(14)

where \( c_{\text{con}} = \sqrt{\frac{H}{13.2R_{\text{hyd}}}} \), using \( \theta_{\text{ax}} = R_{\text{vent}} \times P \) given in [2] the thermal resistance of air ventilation is obtained as Eqn. 15.

\[ R_{\text{vent}} = \frac{1}{c_{\text{con}} \sqrt{\theta_{\text{ax}}}} \]  

(15)

Thermal resistance between the cabinet inside air and the cabinet wall and ceiling is as:

\[ R_{\text{indoor-w & c}} = \frac{1}{\alpha S_{w \& c}} + \frac{d_{w \& c}}{\lambda_{w \& c} S_{w \& c}} \]  

(16)

Thermal resistance between the cabinet inside air and the cabinet door is as:

\[ R_{\text{indoor-door}} = \frac{1}{\alpha S_{d}} + \frac{d_{d}}{\lambda_{d} S_{d}} \]  

(18)

Thermal resistance between the cabinet door with outside ambient is as:

\[ R_{\text{door-amb}} = \frac{1}{\alpha S_{d}} \]  

(19)

The outer heat transfer coefficient can be calculated as Eqn. 20.

\[ \alpha_{o} = 3.958 + 4.304 \nu_{o} \]  

(20)

The inner heat transfer coefficient can be calculated as Eqn. 21.

\[ \alpha_{i} = 3.958 + 4.304 \nu_{i} \]  

(21)

The velocity inside of prefabricated substation can be calculated as Eqn. 22.

\[ \nu = \sqrt{\frac{g H \theta_{\text{ax}}}{273 + \theta_{\text{ax}} + \theta_{\text{amb}}}} \]  

(22)

The extended model of [2] can be simplified as Fig. 3. Using the given model Eqn. 23 is derived.

\[ R_{\text{vent-amb}} = R_{\text{ax}} \left( (R_{\text{ax}} + R_{\text{w & c}}) (R_{\text{ax}} + R_{\text{door-amb}}) \right) \]  

(23)
C\text{\textsubscript{indoor}} is equal to 0.022 times of weight of the prefabricated transformer substation [2].

From solving thermal model given in Fig. 3 the following equations are derived.

\[ q_{j} + q_{i} = C_{\text{th-oil}} \times \frac{d\theta_{o} - \theta_{\text{air-room}}}{dt} \times R_{\text{th-oil-room}} \]  
(24)

\[ q_{j} + q_{i} + q_{\text{cool}} = C_{\text{indoor}} \times \frac{d\theta_{\text{air-room}} - \theta_{\text{amb}}}{dt} \times R_{\text{amb-amb}} \]  
(25)

**C. Hot-Spot Temperature rise modeling**

Similar to the theory given for the top-oil temperature model, the hot-spot temperature model is also represented as a thermal circuit (Fig. 4).

The result obtained from applying the energy balance theorem to the thermal circuit shown in Fig. 5 is:

\[ q_{c} + q_{j} = C_{\text{th-oil}} \times \frac{d\theta_{\text{hx-oil}}}{dt} \times \frac{\theta_{\text{hx-oil}} - \theta_{\text{oil}}}{R_{\text{th-hx-oil}}} \]  
(30)

Fig. 6. shows the hot-spot and top-oil models for two different situations of outdoor and indoor.

\[ R_{\text{th-hx-oil}} = R_{\text{th-oil}} \]  
(29)

\[ R_{\text{th-oil}} = R_{\text{th-ins}} \]  
(28)

\[ R_{\text{th-oil}} = R_{\text{th-wdg}} \]  
(27)

**IV. EXPERIMENTAL TEMPERATURE RISE TESTS**

To verify the models derived for outdoor and indoor transformers the experiments were carried out on a transformer under indoor and outdoor situations. The temperature rise results obtained from experimental tests and theoretical study
for indoor and outdoor transformers are shown in Fig. 7, 8 and 9. In these tests, power injected to the primary windings of the transformer (secondary windings are short circuited) [1, 4, 7] are equal. The figures verify the fact that for the same load and the same conditions, the top-oil and hot-spot temperatures of indoor transformer are higher than those for outdoor transformer.

Fig. 7 shows the experimental results for top-oil and ambient temperatures and the results obtained using the top-oil and hot-spot thermal models for outdoor situation. In this figure, the top oil experimental results are also compared with simulation results of the derived model.

Fig. 8 shows the experimental results for top-oil and ambient temperatures and the results obtained using the top-oil and hot-spot thermal models for indoor situation. In this figure, the top oil experimental results are also compared with simulation results of the derived model.

The top-oil and hot-spot results for indoor and outdoor situations are compared in Fig. 9.

The temperature difference between the hot-spot and top-oil temperatures for two different situations of indoor and outdoor are shown and compared in Fig. 10.

V. CONCLUSION

The hot-spot thermal models of oil immersed power transformer are derived for indoor and outdoor situation. In the hot-spot models proposed for both situations, the variation of ambient temperature is also considered. For the indoor situation, the thermal resistance and the thermal capacitances of different parts of the cabinet, the capacitance effect of “ring main unit” (RMU), and also the power losses of all enclosure components used in service are considered.

An important difference between the top-oil and hot-spot temperatures for two different operating cases (indoor and outdoor) is that, for the same input power, the top-oil and hot-spot temperature of indoor transformer is higher than that for outdoor (Fig. 9). The difference between the hot-spot and top-oil temperatures for two different situations are nearly equal for steady state duration but the corresponding temperature difference is lower for indoor situation than that for outdoor operation for load starting duration or transient (Fig. 10).

Another important point is that, in loading management of transformers the hot-spot temperature should be considered as reference instead of the top-oil temperature. This is due to lower thermal time constant of the hot-spot temperature with respect to thermal time constant of the top-oil temperature.
