Gastroprotective Activity of Swietenia Mahagoni Seed Extract on Ethanol-Induced Gastric Mucosal Injury in Rats

Salma Saleh Alrdaha, Mahmood Ameen Abdullah, Shaharudin Abul Razak, Farkaad Abdul Kadir, Pouya Hassandarvish

Abstract—Swietenia mahagoni have been used in traditional medicine for treatment of different diseases. Present study was performed to evaluate anti-ulcerogenic activity of ethanol seed extract against ethanol induced gastric mucosal injury in rats. Six groups of rats were orally pre-treated respectively with carboxymethyl cellulose, omeprazole 20 mg/kg, 50, 100, 200 and 400 mg/kg plant extract one hour before oral administration of absolute ethanol to generate gastric mucosal injury. After additional hour, rats were sacrificed and ulcer areas of gastric walls were determined. Grossly, carboxymethyl cellulose group exhibited severe mucosal injury, whereas pre-treatment with plant extract exhibited significant protection of gastric mucosa. Histology, carboxymethyl cellulose group exhibited severe damage of gastric mucosa; edema and leucocytes infiltration of sub mucosa compared to plant extract which group exhibited mild damage of gastric mucosa; edema and leucocytes infiltration of sub mucosa compared to plant extract which showed gastric protection. Acute toxicity study did not manifest any toxicological signs in rats. Conclusions, results suggest that S. mahagoni promotes ulcer protection as ascertained grossly and histologically.

Keywords—Cytoprotection, Gastric ulcer, Histology, Swietenia mahagoni seed.

I. INTRODUCTION

Swietenia mahagoni (Linn.) Jacq. (Meliaceae) is a large, deciduous, and economically important timber tree native to the West Indies. This tree is mainly cultivated at tropical zones, such as India, Malaysia, and Southern China [1]. This plant has various types of medicinal values like anti-malarial and anti-diarrhoeal activities [2]-[3]. The plant extracts have been accounted to possess antibacterial and antifungal activities [4]. Limonoids obtained from S. mahagoni have antifungal activity [5] and diabetes therapy [6]. S. mahagoni seeds have been used as folk medicine for the treatment of hypertension, diabetes, and malaria [7], and they have also been reported to have medicinal value for treatment of cancer, amoebiasis, coughs, chest pains and intestinal parasitism. The biologically active ingredients, tetranortriterpenoids and fatty acids, are considered to be responsible for these therapeutic effects [8]. Swietenia mahagoni may have potent antioxidant and antimicrobial activity [9]-[10]. Thus far, there is no data available on gastro-protective activity of S. mahagoni crude extract. The present study was undertaken to evaluate anti-ulcerogenic properties of ethanol crude extract of S. mahagoni seeds in rats.

II. MATERIALS AND METHOD

A. Omeprazole

Omeprazole is a proton pump inhibitor has been widely used as acid inhibitor agents for the treatment of disorders related to gastric acid secretion for about 15 years [11]. Omeprazole is substituted benzimidazoles and it inhibits acid secretion by acting on the hydrogen-potassium exchanger (H+:K+-ATPase) for the apical plasma membrane of the gastric mucosa [12]. Omeprazole is highly selective for the proton pump and undergo catalyzed conversion into active form within the acid forming space. The active inhibitors react with SH (thiol) group of the proton pump, resulting in inhibition of acid formation [13]. In this study, omeprazole was used as the reference anti-ulcer drug, and was obtained from the University Malaya Medical Centre (UMMC) Pharmacy. The drug was dissolved in carboxymethyl cellulose (CMC) and administered orally to the rats in concentrations of 20 mg/kg body (5 ml/kg) [14].

B. Plant specimen and extract preparation

Swietenia mahagoni seed were obtained from Ethno Resources Sdn Bhd, Selangor, Malaysia, and identified by comparison with the Voucher specimen deposited at the Herbarium of Rimba Ilmu, Institute of Science Biology, University of Malaya, Kuala Lumpur. The seeds were shade-dried for 7-10 days and was then finely powdered using electrical blender. One hundred grams of fine powder was soaked in 500 ml of 95% ethanol in conical flask for 3 days. After 3 days, the mixture was filtered using a fine muslin cloth followed by filter paper (Whatman No. 1) and distilled under reduced pressure in an Eyela rotary evaporator (Sigma-Aldrich, USA). The dry extract was then dissolved in...
carboxymethyl cellulose (CMC, 0.25% w/v) and administered orally to rats in concentrations of 50, 100, 200, 400 and 800 mg/kg body weight (5 ml/kg body weight) [15].

C. Acute toxicity test

Experimental animals

Adult healthy male and female Sprague Dawley rats (6-8 weeks old) were obtained from the Animal House, Faculty of Medicine, University of Malaya, Kuala Lumpur (Ethics No. PM 07/05/2008 MAA (a) (R)). The rats weighed between 150 – 180 g. The animals were given standard rat pellets and tap water. The acute toxic study was used to determine a safe dose for the rhizome extract. Thirty six Sprague Dawley rats (18 males and 18 females) were assigned equally each into 3 groups labelled as vehicle (CMC, 0.25% w/v, 5 ml/kg); 2 g/kg and 5 g/kg of Swietenia mahagoni seed extract preparation, respectively. The animals were fasted overnight (food but not water) prior to dosing. Food was withheld for a further 3 to 4 hours after dosing. The animals were observed for 30 min and 2, 4, 8, 24 and 48 h after the administration for the onset of clinical or toxicological symptoms. Mortality, if any was observed over a period of 2 weeks. The acute toxicity LD$_{50}$ was calculated as the geometric mean of the dose that resulted in 100% lethality and that which caused no lethality at all. The mortality in the above-mentioned doses at the end of 14 days macroscopic finding at any time of observation. There was no abnormal signs, behavioural changes, body weight changes, or significant visible of toxicity at these doses. There were no significant.

D. Anti-ulcer activity

Sprague Dawley healthy adult male rats were obtained from the Experimental Animal House, Faculty of Medicine, University of Malaya, and Ethic No. PM/27/07/2009/MAA (R). The rats were divided randomly into 6 groups of 6 rats each. Each rat that weighted between 200 - 225 g was placed individually in separate cage (one rat per cage) with wide-mesh wire bottoms to prevent coprophagia during the experiment. The animals were maintained on standard pellet diet and tap water. The study was approved by the Ethics Committee for animal experimentation, Faculty of Medicine, University of Malaya, Malaysia. All animals received human care according to the criteria outlined in the “Guide for the Care and Use of laboratory Animals” prepared by the National Academy of Sciences and published by the national Institute of health.

E. Gastric ulcer-induction by ethanol and tissue sample collection

The rats were fasted for 48 hours before the experiment [18], but were allowed free access drinking water up till 2 hours before the experiment. Gastric ulcer in Sprague Dawley was induced by orogastric intubation of absolute ethanol (5 ml/kg) according to the method described by [15] with slight modification. Ulcer control group was orally administered with vehicle (CMC, 0.25% w/v, 5ml/kg). The reference group was received oral doses of 20 mg/kg omeprazole in CMC (5 ml/kg) as positive controls. Experimental groups were orally administered with 50, 100, 200 and 400 mg/kg of crude ethanol extract of S. mahagoni seed in CMC solution (5 ml/kg) each, respectively. One hour after this pre-treatment; all groups of rats were administered with absolute ethanol (5 ml/kg) in order to induce gastric ulcers except normal control group which administered CMC (5 ml/kg) [19]. The rats were euthanized by cervical dislocation 60 minutes later [20] under over dose of diethyl ether anaesthesia and their stomachs were immediately excised.

F. Gross gastric lesions evaluation

Any ulcers would be found in the gastric mucosa, appearing as elongated bands of hemorrhagic lesions parallel to the long axis of the stomach. Each gastric mucosa was thus examined for damage. The length (mm) and width (mm) of the ulcer on the gastric mucosa were measured by a planimeter (10 × 10 mm$^2$ = ulcer area) under dissecting microscope (1.8x). The area of each ulcer lesion was measured by counting the number of small squares, 2 mm × 2 mm, covering the length and width of each ulcer band. The sum of the areas of all lesions for each stomach was applied in the calculation of the ulcer area (UA) wherein the sum of small squares $\times 4 \times 1.8 = UA$ mm$^2$) as described by [21] with slight modification. The inhibition percentage (I%) was calculated by the following formula as described by [22] with slight modification.

$$I(\%) = \left[\frac{UA_{control} - UA_{treated}}{UA_{control}}\right] \times 100\%.$$  

G. Histological evaluation of gastric lesions

Specimens of the gastric walls from each rat were fixed in 10% buffered formalin and processed in a paraffin tissue processing machine. Sections of the stomach were made at a thickness of 5 µ and stained with haematoxylin and eosin for histological evaluation.

H. Statistical analysis

All values were reported as mean ± S.E.M. The statistical significance of differences between groups was assessed using one-way ANOVA. A value of $p<0.05$ was considered significant.

III. RESULT

A. Acute toxicity study

Acute toxicity study in which the animals treated with the rhizome extract at a dose of 2 g/kg and 5 g/kg of Swietenia mahagoni seed extracts were kept under observation for 14 days. All the animals remain alive and did not manifest any significant visible of toxicity at these doses. There were no abnormal signs, behavioural changes, body weight changes, or macroscopic finding at any time of observation. There was no mortality in the above-mentioned doses at the end of 14 days of observation. Histology of liver and kidney, haematology
and serum biochemistry revealed no significant differences between groups. From these results it is concluded that the extract is quite safe even at these higher doses and has no acute toxicity and the oral lethal dose (LD₅₀) for the male and female rats were greater than their 5 g/kg body weight.

B. Gross evaluation of gastric lesions

The anti-ulcer activity of S. mahagoni seed extract in ethanol-induced gastric lesion model is reported in Table 1. Results showed that rats pre-treated with S. mahagoni seed extracts before being given absolute alcohol had significantly reduced areas of gastric ulcer formation compared to rats pre-treated with only CMC (ulcer control group) (Figure 1 a, b and c). Moreover, the seed extract significantly suppressed the formation of the ulcers and it was interesting to note the flattening of gastric mucosal folds in rats pre-treated with S. mahagoni seed extract. It was also observed that protection of gastric mucosa was more prominent in rats pre-treated with 400 mg/kg rhizome extract (Table 1). Beside, ethanol-induced mucosal damage was significantly reduced in size and severity by pre-treatment of the animals with S. mahagoni seed extract. The significant inhibition of gastric ulcer in pre-treatment with rhizome extract was compared with omeprazole which is a standard drug used for curing gastric ulcer.

C. Histological evaluation of gastric lesions

Histological observation of ethanol induced gastric lesions in ulcer control group pre-treated with only CMC, showed comparatively extensive damage to the gastric mucosa, and oedema and leucocytes infiltration of the sub-mucosal layer (Figure 2a). Rats that received pre-treatment with S. mahagoni seed extract had comparatively better protection of the gastric mucosa as seen by reduction in ulcer area, reduced or absence of sub-mucosal oedema and leucocytes infiltration (Figure 2b and c). The S. mahagoni seed extract has been shown to exert the cytoprotective effects in a dose-dependent manner.

All values are expressed as mean ± standard error mean. Means with different superscripts are significantly different. The mean difference is significant at the 0.05 level.
mild oedema and leucocytes infiltration of the sub-mucosal layer. “(c)” pre-treated with 5 ml/kg of Swietenia mahagony seed extract (400 mg/kg). There is very mild disruption to the surface epithelium with no oedema and no leucocytes infiltration of the sub-mucosal layer (H&E stain 10x).

IV. DISCUSSION

Peptic ulcers are caused when the natural balances between the aggressive factors of acid and pepsin and defensive mechanisms of mucus, bicarbonate, mucosal turnover and blood supply (mucosal barrier) are disturbed [23]. Reference [24] have suggested that acid and pepsin are relatively less important as causative agents and that a defect in the defensive mechanism of gastric mucosa is the first step toward ulcer formation. Although in most cases the aetiology of ulcer is unknown, it is generally accepted that it is the result of an imbalance between aggressive factors and maintenance of the mucosal integrity through the endogenous defence mechanisms [23]. It is known that gastric lesions produced by ethanol administration appeared as multiple-hemorrhagic red bands of different size along the glandular stomach. Ethanol is commonly used for inducing ulcer in experimental rats and lead to intense gastric mucosal damage. Studies suggest that the ethanol damage to the gastrointestinal mucosa starts with micro-vascular injury, namely disruption of the vascular endothelium resulting in increased vascular permeability, oedema formation and epithelial lifting [25]. Ethanol produces necrotic lesions in the gastric mucosa by its direct toxic effect, reducing the secretion of bicarbonates and production of mucus [26]. Exposure to ethanol increases the extension of cellular damage in a dose-dependent way [27]. Oxidative stress plays an important role in the pathogenesis of various diseases including gastric ulcer, with antioxidants being reported to play a significant role in the protection of gastric mucosa against various necrotic agents [28]. Antioxidants could help to protect cells from damage caused by oxidative stress while enhancing the body’s defence systems against degenerative diseases. Administration of antioxidants inhibits ethanol-induced gastric injury in rat [29]. Swietenia mahagony seed crude extract possess a broad spectrum of biological activities and the plant extract have been shown to contain relatively large quantity antioxidant compounds [9] and it is speculated that the gastroprotective exerted by Swietenia mahagony seed extract could be attributed to its antioxidant property. The result of the present study also revealed protection of gastric mucosa and inhibition of leucocytes infiltration of gastric wall in rats pre-treated with Swietenia mahagony seed extract. Similarly, [30] reported that teprenone exerts a protective effect against mucosal lesions through inhibition of neutrophil infiltration in the ulcerated gastric tissue and [31] demonstrated that the reduction of neutrophil infiltration into ulcerated gastric tissue promotes the healing of gastric ulcers in rats. Reference [32] showed that oral administration of plant extract before ethanol administration significantly decreased neutrophil infiltration of gastric mucosa and [33] observed that an increase in neutrophil infiltration into ulcerated gastric tissue delayed the healing of gastric ulcers in rats. Absolute alcohol would extensively damage the gastric mucosa leading to increased neutrophil infiltration into the gastric mucosa. Oxygen free radicals derived from infiltrated neutrophils in ulcerated gastric tissues have inhibitory effect on gastric ulcers healing in rats [34]. Neutrophils mediate lipid peroxidation through the production of superoxide anions [35]. In the present study, we observed flattening of the mucosal folds which suggests that gastroprotective effect of Swietenia mahagony seed extract might be due to a decrease in gastric motility. It is reported that the changes in the gastric motility may play a role in the development and prevention of experimental gastric lesions [36-37]. Relaxation of circular muscles may protect the gastric mucosa through flattening of the folds. This will increase the mucosal area exposed to necrotizing agents and reduce the volume of the gastric irritants on fugal crest [38]. Ethanol produces a marked contraction of the circular muscles of rat fundic strip. Such a contraction can lead to mucosal compression at the site of the greatest mechanical stress, at the crests of mucosal folds leading to necrosis and ulceration [39]. The acute toxicity profile of B. rotunda rhizome extract could be considered favourable judging from the absence of adverse clinical manifestations in experimental animals after 14 days of observation. It is concluded that the extract has no acute toxicity and that the oral lethal dose for male and female rats is in excess of 5 g/kg. In conclusion, Swietenia mahagony seed extracts could significantly protect the gastric mucosa against ethanol-induced injury. Such protection was shown to be dose dependent as ascertained by the reduction of ulcer areas in the gastric wall as well as the reduction or inhibition of oedema and leucocytes infiltration of sub-mucosal layers, and protection was most prominent at a dose of 400 mg/kg rhizome extract. Further studies are required to determine the active ingredients responsible for the mechanism of antulcer of Swietenia mahagony seed extracts.

ACKNOWLEDGMENT

The authors express gratitude to the staff of the Faculty of Medicine Animal House for the care and supply of rats, and to the University of Malaya for the financial support (P0102/2009 C).
