Bifurcations of a delayed prototype model

Changjin Xu

Abstract—In this paper, a delayed prototype model is studied. Regarding the delay as a bifurcation parameter, we prove that a sequence of Hopf bifurcations will occur at the positive equilibrium when the delay increases. Using the normal form method and center manifold theory, some explicit formulae are worked out for determining the stability and the direction of the bifurcated periodic solutions. Finally, Computer simulations are carried out to explain some mathematical conclusions.

Keywords—Prototype model; Stability; Hopf bifurcation; Delay; Periodic solution.

I. INTRODUCTION

In 2002, Uc¸ar[1] investigated the following simple nonlinear system with delay element

\[
\frac{dx(t)}{dt} = \delta x(t-\tau) - \epsilon x(t-\tau)^3, (t \geq t_0),
\]

where \(\delta\) and \(\epsilon\) are positive parameters; \(t_0\) is the initial interval and \(\tau > 0\) corresponds to the delay time in which represents the time interval between the start of an event at one point and its resulting action at another point in the system. Uc¸ar[1] presented the rich dynamical behaviors of system (1) by means of fifth-order Runge-Kutta ordinary differential solver, embedded in Matlab toolboxes. It has been shown that the simple system (1) with a time delay can exhibit very complex behavior include chaos and it can be used as a prototype model for investigating chaotic behaviors in engineering science. In 2003, Uc¸ar[2] further studied the model (1). The effect of delay on the global behaviors of system (1) had been analyzed with the bifurcation diagram for a range of the delay time. By use of the Euler method and Runge-Kutta discretization, Peng[3] proposed a discrete version of system (1) as follows

\[
u(k+1) = u(k) + \alpha(\delta, \tau, n)u(k-n) - \beta(\epsilon, \tau, n)u(k-n)^3,
\]

where \(\alpha(\delta, \tau, n) = \delta \tau/n, \beta(\epsilon, \tau, n) = \epsilon \tau/n\) and \(u(k)\) is an approximate value to \(x(kh), h = 1/n\) is a step-size. In [3], efficient computation of Hopf bifurcation, stable limit cycle(periodic solutions), symmetrical breaking bifurcations and chaotic behavior of system (2) was proposed. In order to investigate the effect of parameters of system, Li et al.[4] made an discussion on the Hopf bifurcation of following system

\[
\frac{dx(t)}{dt} = ax(t-\tau) - b[x(t-\tau)]^3,
\]

which is in fact equivalent to system (1). By choosing the coefficient \(a\) as a bifurcation parameter, the local stability and the existence of Hopf bifurcation were considered. Moreover, the stability of bifurcating periodic solutions and the direction of Hopf bifurcation were determined by applying the normal form theory and center manifold theorem.

Based on former work[1-4], we further devote to explore the dynamical behaviors of system (1), i.e., by regarding the delay as bifurcation parameter, we will investigate the natures of Hopf bifurcation of system (1). In recent years, there are a number of papers which deal with this topic(see[5-19]).

This paper is organized as follows. In Section 2, the stability of the equilibrium and the existence of Hopf bifurcation at the equilibrium are studied. In Section 3, the direction of Hopf bifurcation and the stability and periodic of bifurcating periodic solutions on the center manifold are determined. In Section 4, numerical simulations are carried out to illustrate the validity of the main results. Some main conclusions are drawn in Section 5.

II. STABILITY OF THE EQUILIBRIUM AND LOCAL HOPF BIFURCATIONS

Considering the biological interpretations of population, in this paper, we only investigated the positive equilibrium point of system (1). It is obvious that system (1) has a unique positive equilibrium point \(x^* = \sqrt{\frac{\delta}{\epsilon}}\).

Let \(\bar{x}(t) = x(t) - x^*,\) Substituting this into (1) and still denote \(\bar{x}(t)\) by \(x(t),\) then (1) takes the form

\[
\frac{dx(t)}{dt} = -2\delta x(t-\tau) - 3\sqrt{\delta} x^2(t-\tau) - \epsilon x^3(t-\tau),
\]

Then the linearization of system (4) at the equilibrium \((0,0)\) is given by

\[
\frac{dx(t)}{dt} = -2\delta x(t-\tau),
\]

whose associated characteristic equation of (5) takes the form

\[
\lambda + 2\delta e^{-\lambda \tau} = 0,
\]

Let \(\lambda = i\omega_0, \tau = \tau_0,\) and substituting this into (5). Separating the real and imaginary parts, we get

\[
2\delta \cos \omega_0 \tau = 0, 2\delta \sin \omega_0 \tau = \omega_0.
\]

Since \(a_1 < 0,\) then it is easy to obtain

\[
\omega_0 = 2\delta, \tau = \tau_k = \frac{1}{2\delta} \left[k \pi + \frac{\pi}{2}\right], k = 0, 1, 2, \cdots.
\]

Note that when \(\tau = 0,\) (6) becomes

\[
\lambda = -2\delta < 0.
\]

The above analysis leads to

**Lemma 2.1.** System (1) admits a pair of purely imaginary roots \(\pm \omega_0\) when \(\tau = \tau_k, k = 0, 1, 2, \cdots\).

Let \(\lambda(\tau) = \alpha(\tau) + i\omega(\tau)\) be the root of Eq.(6) near \(\tau = \tau_k\) satisfying \(\alpha(\tau_k) = 0, \omega(\tau_k) = \omega_0.\) Due to functional
differential equation theory, for every $\tau_k, k = 0, 1, 2 \cdots$, there exists a $\varepsilon > 0$ such that $\lambda(\tau)$ is continuously differentiable in $\tau$ for $|\tau - \tau_k| < \varepsilon$. Substituting $\lambda(\tau)$ into the left hand side of (6) and taking the derivative of $\lambda$ with respect to $\tau$, we get

$$\left[\frac{d\lambda}{d\tau}\right]^{-1} = \frac{1}{2\delta \lambda e^{-\lambda \tau}} \tau, \lambda.$$ 

It follows together with (7) that

$$\text{Re} \left[\frac{d\lambda}{d\tau}\right]^{-1} = \text{Re} \left\{ \frac{1}{2\delta \lambda e^{-\lambda \tau}} \right\} = \frac{\sin \omega_0 \tau_k}{2\delta \omega_0} = \frac{1}{2\delta} > 0.$$ 

Thus

$$\text{sign} \left( \text{Re} \left[\frac{d\lambda}{d\tau}\right]^{-1} \right) = \text{sign} \left( \text{Re} \left[\frac{d\lambda}{d\tau}\right]^{-1} \right) > 0.$$ 

According to the results of Kuang[20] and Hale[21], we have

**Theorem 2.1.** The positive equilibrium $x^*$ of system (1) is asymptotically stable for $\tau \in [0, \tau_0)$ and unstable for $\tau \geq \tau_0$. System (1) undergoes a Hopf bifurcation at the positive equilibrium $x^*$ when $\tau = \tau_k, k = 0, 1, 2 \cdots$.

### III. Direction and Stability of the Hopf Bifurcation

In the previous section, we have obtained conditions for Hopf bifurcation to occur when $\tau = \tau_k$. In this section, we shall derive the explicit formulae for determining the direction, stability, and period of these periodic solutions bifurcating from the equilibrium $x^*$ at these critical value of $\tau$, by using techniques from normal form and center manifold theory [22]. Throughout this section, we always assume that system (4) undergoes Hopf bifurcation at the equilibrium $x^*$ for $\tau = \tau_k$, and then $\pm i\omega_0$ are corresponding purely imaginary roots of the characteristic equation at the equilibrium $x^*$.

For convenience, let $\tilde{x}(t) = x(\tau t), \tau = \tau_k + \mu$ and still denote $\tilde{x}(t)$ by $x(t)$, then system (4) can be written as an FDE in $C = C[-1,0]$, $R$ as

$$\tilde{x}(t) = L_{\mu}(x(t)) + f(x(t), \tau), \quad \mu \in C[-1,0], R$$

where $\mu \in C[-1,0]$, and $L_{\mu}: C \to R, f: R \times C \to R$ are given by

$$L_{\mu}(\phi) = -(\tau_k + \mu)g(\phi(-1)), \quad f(\mu, \phi) = (\tau_k + \mu)[-3\sqrt{3} \delta \phi^2(-1) - \epsilon \phi^3(-1)].$$

From the discussions in Section 2, we know that if $\mu = 0$, then system (10) undergoes a Hopf bifurcation at the zero equilibrium and the associated characteristic equation of system (10) has a pair of simple imaginary roots $\pm i\omega_0\tau_k$.

By the Riesz representation theorem, there exists a matrix whose components are bounded variation functions $\eta(\theta, \mu)$ in $[-1,0] \to R$, such that

$$L_{\mu}\phi = \int_{-1}^{0} d\eta(\theta, \mu)\phi(\theta).$$

In fact, choosing

$$\eta(\theta, \mu) = 2\delta \delta_1(\theta + 1), \quad \delta_1(\theta) \text{ is Dirac delta function},$$

we have

$$A(\mu) = \int_{-1}^{0} d\eta(\theta, \mu) \phi(\theta), \quad \theta = 0$$

and

$$R(\mu) = \int_{-1}^{0} f(\mu, \phi), \quad -1 \leq \theta < 0, \quad \theta = 0.$$
real, we consider only real solutions. For solutions $x_t \in C_0$ of (1),
\[
\dot{z}(t) = \frac{\partial^2}{\partial t^2} z(t) = q^*(s) \dot{x}_t + f(0, x_t) \dot{t}.
\]
where
\[
g(z, \bar{z}) = g_{20} \epsilon z^2 + g_{11} z \bar{z} + g_{02} \epsilon z^2 + g_{21} \epsilon z^2 \bar{z} + \cdots.
\]
Hence, we have
\[
g(z, \bar{z}) = q^*(0) f_0(z, \bar{z}) = q^*(0) f_0(0, x_t) = D f_0(0, x_t),
\]
where
\[
f_0(0, x_t) = \tau_k \left[ -3 \sqrt{\bar{\jmath}e_{x_t^2}(1) - e_{x_t^2}(1)} \right].
\]
Noticing that $x_t(\theta) = W(t, \theta) + \epsilon z(\theta) + \bar{z}(\theta)$ and $q(\theta) = \epsilon e^{i\omega_0 \tau_k \theta}$, we have
\[
x_t(0) = z + \bar{z} + W_{20}(0) \epsilon z^2 + W_{11}(0) z \bar{z} + W_{02}(0) \epsilon z^2 + \cdots,
\]
\[
x_t(-1) = e^{-i\omega_0 \tau_k \theta} z + e^{i\omega_0 \tau_k \theta} z + W_{20}(-1) \epsilon z^2 + W_{11}(-1) z \bar{z} + W_{02}(-1) \epsilon z^2 + \cdots.
\]
It follows from (26) that
\[
g(z, \bar{z}) = q^*(0) f_0(z, \bar{z}) = D f_0(0, x_t)
\]
where
\[
g(z, \bar{z}) = \frac{\partial^2}{\partial t^2} z(t) = q^*(0) f_0(z, \bar{z}) = q^*(0) f_0(0, x_t) = D f_0(0, x_t),
\]
where
\[
f_0(0, x_t) = \tau_k \left[ -3 \sqrt{\bar{\jmath}e_{x_t^2}(1) - e_{x_t^2}(1)} \right].
\]
Noticing that $x_t(\theta) = W(t, \theta) + \epsilon z(\theta) + \bar{z}(\theta)$ and $q(\theta) = \epsilon e^{i\omega_0 \tau_k \theta}$, we have
\[
x_t(0) = z + \bar{z} + W_{20}(0) \epsilon z^2 + W_{11}(0) z \bar{z} + W_{02}(0) \epsilon z^2 + \cdots,
\]
\[
x_t(-1) = e^{-i\omega_0 \tau_k \theta} z + e^{i\omega_0 \tau_k \theta} z + W_{20}(-1) \epsilon z^2 + W_{11}(-1) z \bar{z} + W_{02}(-1) \epsilon z^2 + \cdots.
\]
It follows from (26) that
\[
g(z, \bar{z}) = q^*(0) f_0(z, \bar{z}) = D f_0(0, x_t)
\]
where
\[
g(z, \bar{z}) = \frac{\partial^2}{\partial t^2} z(t) = q^*(0) f_0(z, \bar{z}) = q^*(0) f_0(0, x_t) = D f_0(0, x_t),
\]
where
\[
f_0(0, x_t) = \tau_k \left[ -3 \sqrt{\bar{\jmath}e_{x_t^2}(1) - e_{x_t^2}(1)} \right].
\]
From (38), (39) and the definition of $A$, we have

$$
\begin{align*}
-2\delta W_{20}(-1) &= 2i\omega_0\tau_k W_{20}(0) - H_{20}(0), \\
-2\delta W_{11}(-1) &= -H_{11}(1).
\end{align*}
$$

(42)

Noting that

$$
\left(i\omega_0\tau_k I - \int_{-1}^{0} e^{i\omega_0\tau_k \theta} d\eta(\theta)\right) q(0) = 0,
$$

(43)

and substituting (35) and (40) into the first equation of (42), we have

$$
\left(2i\omega_0 + 2\delta e^{-2i\omega_0\tau_k}\right) E_1 = -2\left(3\tau_k \sqrt{\delta e^{-2i\omega_0\tau_k}}\right).
$$

(45)

That is

$$
\left(2i\omega_0 + 2\delta e^{-2i\omega_0\tau_k}\right) E_1 = -2\left(3\sqrt{\delta e^{-2i\omega_0\tau_k}}\right).
$$

Thus

$$
E_1 = \frac{-3\sqrt{\delta e^{-2i\omega_0\tau_k}}}{i\omega_0 + \delta e^{-2i\omega_0\tau_k}}.
$$

(46)

Similarly, substituting (37) and (41) into the second equation of (42), we have

$$
\left(\int_{-1}^{0} d\eta(\theta)\right) E_2 = -2\left(3\tau_k \Re\{e^{i\omega_0\tau_k}\}\right).
$$

(47)

That is

$$
2\delta E_2 = 2\left(3\Re\{e^{i\omega_0\tau_k}\}\right),
$$

which leads to

$$
E_2 = \frac{3\Re\{e^{i\omega_0\tau_k}\}}{\delta}.
$$

(48)

In view of (35), (37), (46) and (48), we can calculate $g_{21}$ and derive the following values:

$$
\begin{align*}
c_1(0) &= \frac{i}{2i\omega_0\tau_k} \left(\frac{g_{20}g_{11} - 2|g_{11}|^2 - \frac{|g_{22}|^2}{3}}{3} + \frac{g_{21}}{2}\right), \\
\mu_2 &= -\frac{\Re\{c_1(0)\}}{\Re\{\lambda'(\tau_k)\}}, \quad \beta_2 = 2\Re(c_1(0)), \\
T_2 &= -\frac{\Im\{c_1(0)\} + \mu_2\Im\{\lambda'(\tau_k)\}}{\omega_0\tau_k},
\end{align*}
$$

which give a description of the Hopf bifurcation periodic solutions of (1) at $\tau = \tau_k$ on the center manifold. From the discussion above, we have the following result.

**Theorem 3.3.** For system (1), if (H) holds, the periodic solution is supercritical (subcritical) if $\mu_2 > 0$ ($\mu_2 < 0$); The bifurcating periodic solutions are orbitally asymptotically stable with asymptotic phase (unstable) if $\beta_2 < 0$ ($\beta_2 > 0$); The periods of the bifurcating periodic solutions increase (decrease) if $T_2 > 0$ ($T_2 < 0$).

In this section, to illustrate the analytical results found, let us consider the following special case of system (1)

$$
\frac{dx(t)}{dt} = 0.6x(t - \tau) - 2[x(t - \tau)]^3,
$$

(49)

which has a unique positive equilibrium $x^* \approx 0.5477$. It follows from Theorem 2.1 that $\omega_0 \approx 1.2083, \tau_0 \approx 1.3002$. By means of Matlab 7.0, we get $\lambda'(\tau_0) \approx 1.2055 - 0.3847i, c_1(0) \approx -1.4535 - 7.0342i, \mu_2 \approx 1.2057, \beta_2 \approx -2.9070, T_2 \approx 0.5401$. Then it follows that $\mu_2 > 0$ and $\beta_2 < 0$. By Theorem 2.1, we know that the positive equilibrium is stable when $\tau < \tau_0$. Figs.1-2 show that the positive equilibrium $x^* \approx 0.5477$ is asymptotically stable when $\tau = 1.2 < \tau_0 \approx 1.3$. A Hopf bifurcation occurs when $\tau = \tau_0$, the positive equilibrium loses its stability and a periodic solution bifurcating from the positive equilibrium occurs for $\tau > \tau_0$. The bifurcation is supercritical and the bifurcating periodic solution is orbitally asymptotically stable. Figs.3-4 show that a family of periodic solutions bifurcate from the positive equilibrium $x^* \approx 0.5477$ when $\tau = 1.4 > \tau_0 \approx 1.3002$. 

Figs.1-2 The trajectories graphs of system (49) with $\tau = 1.2 < \tau_0 \approx 1.3002$ and the initial value 0.8.
some critical values Hopf bifurcation occurs when the delay $\tau$ as bifurcation parameter, it has been shown that Hopf bifurcation in a nonlinear delay population model. By using the normal form theory and center manifold theorem. the stability of the bifurcating periodic orbits are derived by applying the normal form theory and center manifold theorem.

To verify some of the mathematical results, we have taken an example for the model. Computer simulations are carried out for some artificial chosen data.

V. CONCLUSIONS

In this paper, we have investigated the properties of Hopf bifurcation in a nonlinear delay population model. By using the delay as bifurcation parameter, it has been shown that Hopf bifurcation occurs when the delay $\tau$ passes through some critical values $\tau = \tau_k, k = 0, 1, 2, \cdots$. This means that a class of periodic orbits bifurcates from the corresponding equilibrium. Moreover, the direction of Hopf bifurcation and the stability of the bifurcating periodic orbits are derived by applying the normal form theory and center manifold theorem.

To verify some of the mathematical results, we have taken an example for the model. Computer simulations are carried out for some artificial chosen data.
