Abstract—The electromagnetic imaging of inhomogeneous dielectric cylinders buried in a slab medium by transverse electric (TE) wave illumination is investigated. Dielectric cylinders of unknown permittivities are buried in second space and scattered a group of unrelated waves incident from first space where the scattered field is recorded. By proper arrangement of the various unrelated incident fields, the difficulties of ill-posedness and nonlinearity are circumvented, and the permittivity distribution can be reconstructed through simple matrix operations. The algorithm is based on the moment method and the unrelated illumination method. Numerical results are given to demonstrate the capability of the inverse algorithm. Good reconstruction is obtained even in the presence of additive Gaussian random noise in measured data. In addition, the effect of noise on the reconstruction result is also investigated.

Keywords—Slab Medium, Unrelated Illumination Method, TE Wave Illumination, Inhomogeneous Cylinders.

I. INTRODUCTION

In the last few years, inverse scattering problems of objects buried in slab medium have been a growing importance in many different fields of applied science, with a large potential impact on geosciences and remote sensing applications. Typical examples are the detection of water pipes buried in the wall, power and communication cables buried in the wall, archaeological remains and so on. However, the solutions are considerably more difficult than those involving objects in free space or a half space. This is due to the interaction between the air-earth interface and the object, which leads to the complicated Green’s function for this three layer problem. Most microwave inverse scattering algorithms developed are for TM wave illuminations in which the vectorial problem can be simplified to a scalar one [1]-[7]. On the other hand, much fewer works have been reported on the more complicated TE case [8]-[13]. In the TE wave excitation case, the presence of polarization charges makes the inverse problem more nonlinear. As a result, the reconstruction becomes more difficult. However, the TE polarization case is useful because it provides additional information about the object. To the best of our knowledge, in TE case, there is still no investigation on the inverse scattering of inhomogeneous dielectric cylinders buried in a slab medium by unrelated illumination method.

In this paper, the inverse scattering of inhomogeneous dielectric cylinders buried in a slab medium by TE wave illumination is investigated. An efficient algorithm is proposed to reconstruct the permittivity distribution of the objects by using only the scattered field measured outside. The algorithm is based on the unrelated illumination method [7], [10], [12]-[13]. In Section II, the theoretical formulation for electromagnetic inverse scattering is presented. Numerical results for objects of different permittivity distributions are given in Section III. Finally, conclusions are drawn in Section IV.

II. THEORETICAL FORMULATION

Let us consider dielectric cylinders buried in a lossless homogeneous half-space as shown in Fig. 1. Where \( (\varepsilon_i, \sigma_i) \) \( i = 1, 2, 3 \), denote the permittivities and conductivities in each region. The permeability is \( \mu_0 \) for all material including the scatterers. The axis of the buried cylinder is the z-axis; that is, the properties of the scatterer may vary with the transverse coordinates only. A group of unrelated incident wave with magnetic field parallel to the z-axis (i.e., transverse electric, or TE, polarization) is illuminated upon the scatterers. Owing to the interface, the incident plane wave generates three waves...
that would exist the absence of the conducting object. Let the unperturbed field be represented by

\[
\mathbf{E}^c(x, y) = \begin{cases} 
(E^c_0)(x, y)^\wedge, & y \geq a, \\
(E^c_1)(x, y)^\wedge, & a > y > -a, \\
(E^c_2)(x, y)^\wedge, & y \leq -a.
\end{cases}
\]

(1)

By using the vector potential techniques, the internal electric field

\[
\mathbf{E}(x, y) = \mathbf{E}^c(x, y)^\wedge + \mathbf{E}_y(x, y)^\wedge = (E^c_0 + E^c_1)^\wedge + (E^c_1 + E^c_2)^\wedge
\]

and the external scattered field,

\[
\mathbf{E}^s(x, y) = E^s_0(x, y)^\wedge + E^s_1(x, y)^\wedge
\]

can be expressed by the following equations:

\[
E^s_0(\vec{r}) = \left( \frac{\partial^2}{\partial x^2} + k^2 \right) \int \mathbf{G}(\vec{r}, \vec{r}') \varepsilon_0(\vec{r}') - 1 E^s_0(\vec{r}') \, d\vec{s}'
\]

\[
E^s_1(\vec{r}) = -\left( \frac{\partial^2}{\partial y^2} + k^2 \right) \int \mathbf{G}(\vec{r}, \vec{r}') \varepsilon_0(\vec{r}') - 1 E^s_0(\vec{r}') \, d\vec{s}'
\]

(2)

\[
E^s_0(\vec{r}) = \left( \frac{\partial^2}{\partial x^2} + k^2 \right) \int \mathbf{G}(\vec{r}, \vec{r}') \varepsilon_0(\vec{r}') - 1 E^s_0(\vec{r}') \, d\vec{s}'
\]

\[
E^s_1(\vec{r}) = -\left( \frac{\partial^2}{\partial y^2} + k^2 \right) \int \mathbf{G}(\vec{r}, \vec{r}') \varepsilon_0(\vec{r}') - 1 E^s_0(\vec{r}') \, d\vec{s}'
\]

(3)

\[
G_{1a}(x, y, x', y') = \frac{1}{2\pi} \int_{\gamma_1} \int_{\gamma_2} \frac{e^{-j\gamma(y-y')}}{\gamma_1 + \gamma_2} \, d\gamma
\]

\[
G_{2a}(x, y, x', y') = G_{2b}(x, y, x', y') + G_{2s}(x, y, x', y')
\]

(4)

(5)

\[
G_{2a}(x, y, x', y') = \frac{1}{2\pi} \int_{\gamma_1} \int_{\gamma_2} \frac{e^{-j\gamma(y-y')}}{\gamma_1 + \gamma_2} \, d\gamma
\]

\[
G_{2a}(x, y, x', y') = G_{2b}(x, y, x', y') + G_{2s}(x, y, x', y')
\]

(6)

(7)

(8)

where \( G_{2b}(x, y, x', y') \) and \( G_{2s}(x, y, x', y') \) represent the \( N \)-element incident field column vectors and, \( E^s_0 \) and \( E^s_1 \) are the \( N \)-element total...
field column vectors. \((E_1')\) and \((E_2')\) denote the M-element scattered field column vectors. Here \(M\) is the number of measurement points. The matrices \([G_1], [G_2], \) and \([G_3]\) are \(N \times N\) square matrices. \([G_1], [G_2], \) and \([G_3]\) are \(M \times N\) matrices. The element in matrices \([G_i], i=1, 2, \ldots \) can be obtained by tedious mathematical manipulation. \((\tau)\) is a \(N \times N\) diagonal matrix whose diagonal element are formed from the permittivities of each cell minus one. \([I]\) is a identity \(N \times N\) matrix.

For the inverse scattering problem, the permittivity distribution of the dielectric objects is to be computed by the knowledge of the scattered field measured in region 1. In the inversion procedure, \(2N\) different incident column vectors are used to illuminate the object, the follow equations are obtained:

\[ [E_1'] = [G_1][\tau] + [I], \quad [E_1'] = [E_1'] \quad (9) \]
\[ [E_2'] = -[G_2][\tau] + [I], \quad [E_2'] = [E_2'] \quad (10) \]

where
\[ [E_1'] = \begin{bmatrix} E_1' \\ E_2' \end{bmatrix}, \quad [E_1] = \begin{bmatrix} E_1 \\ E_2 \end{bmatrix}, \quad [E_2'] = \begin{bmatrix} E_2' \\ E_1' \end{bmatrix} \]
\[ [\tau] = \begin{bmatrix} \tau \\ 0 \\ 0 \end{bmatrix}, \quad [I] = \begin{bmatrix} I \\ 0 \\ 0 \end{bmatrix} \]

Here \([E_1']\) and \([E_2']\) are both \(2N \times 2N\) matrices. \([E_1']\) is a \(M \times 2N\) matrix. It is worth mentioning that other than matrix \([G_i]\), the matrix \([G_i][\tau] + [I]\) is always a well-posed one in any case, therefore we can first solve \([E_1']\) in (9) and substitute into (10), then \(\tau\) can be found by the following equation

\[ [\Psi'][\tau] = [\Phi'] \quad (11) \]

where
\[ [\Phi'] = -(E_1')E_2'^{-1}, \quad [\Psi'] = E_1'E_1'^{-1}[G_1] + [G_2] \]

From (11), all the diagonal elements in the matrix \(\tau\) can be determined by comparing the element with the same subscripts which may be any row of both \([\Psi']\) and \([\Phi']\):

\[ (\tau)_{mn} = (\Phi')_{mn}, \quad n \leq N \quad (12a) \]

or

\[ (\tau)_{(n-N)(n-N)} = (\Phi')_{mn}, \quad n \geq N + 1 \quad (12b) \]

Then the permittivities of each cell can be obtained as follows:

\[ \epsilon = (\tau) + 1 \quad (13) \]

Note that there are a total of \(2M\) possible values for each element of \(\tau\). Therefore, the average value of these \(2M\) data is computed and chosen as final reconstruction result in the simulation. In the above derivation, the key problem is that the incident matrices \([E_1']\) must not be a singular matrix, i.e., all the incident column vectors that form the \([E_1']\) matrices, must be linearly unrelated. Thus, if the object is illuminated by a group of unrelated incident waves, it is possible to reconstruct the permittivity distribution of the objects. Note that when the number of cells becomes very large; it is difficult to make such a great number of independent measurements. In such a case, some regularization methods must be used to overcome the ill-posedness.

### III. Numerical Results

In this section, we report some numerical results obtained by computer simulations using the method described in the Section II. Consider a lossless three-layer structure \(\sigma_1 = \sigma_2 = \sigma_3 = 0\) and the width of the second layer is \(0.2m\). The permittivity in each region is characterized by \(\epsilon_1 = \epsilon_o\), \(\epsilon_2 = 2.25\epsilon_o\) and \(\epsilon_3 = \epsilon_o\) respectively, as shown in Fig. 1. The frequency of the incident wave is chosen to be \(3\) GHz. The incident waves are generated by numerous groups of radiators operated simultaneously.

Each group of radiators is restricted to transmit a narrow-bandwidth pattern that can be implemented by antenna array techniques. By changing the beam direction and tuning the phase of each group of radiators, one can focus all the incident beams in turn at each cell of the object. This procedure is named “beam focusing” [7]. Note that this focusing should be set when the scatterer is absent. Clearly, an incident matrix formed in this way is diagonally dominant and its inverse matrix exists. The measurement is taken from \(0.4m\) to \(-0.4m\) in region 1 at equal spacing. The number of measurement points is set to be 9 for each illumination. For avoiding trivial inversion of finite dimensional problems, the discretization number for the direct problem is four times that for the inverse problem in our numerical simulation.

A the buried cylinder with a \(70 \times 21\) mm rectangular cross section is discretized into \(20 \times 6\) cells, and the corresponding dielectric permittivities are plotted in Fig. 2. The model is characterized by simple step distribution of permittivity. Each cell has \(3.5 \times 3.5\) mm cross-sections. The reconstructed permittivity distributions of the object are plotted in Fig. 3. The root-mean-square (RMS) error is about 0.9\%. It is apparent that the reconstruction is good. For investigating the effect of where \(b\) and \(c\) are independent random numbers having a Gaussian distribution over 0 to the noise level times the rms value of the scattered field. The noise levels applied include \(10^{-5}, 10^{-4}, 10^{-3}, 10^{-2}, \) and \(10^{-1}\) in the simulations. The numerical results for the example is plotted in Fig. 4. They show the effect of noise is tolerable for noise levels below 1% noise, we add to each complex scattered field a quantity \(b+ci\).

Our method depends on the condition number of \([E_1']\); that is, on having \(2N\) unrelated measurements. The procedure will generally not work when the number of unknowns gets very large. This is due to the fact that it is difficult to make such a great number of measurements and make them all unrelated. As a result, the condition number of \([E_1']\) will become large while...
the number of unknowns is very large. In such a case, the
regularization method should be employed to overcome the ill-
posedness. For instance, the pseudoinverse transform
 techniques [7] can be applied for the inversion of the \[E'_i\]
matrix.

IV. CONCLUSIONS

Imaging algorithm for TE case is more complicated than that
for the TM case, due to the added difficulties in the polarization
charges. Nevertheless, the polarization charges cannot be
ignored for this two-dimensional problem and all
three-dimensional problems. In this paper, an efficient
algorithm for reconstructing the permittivity distribution of
inhomogeneous dielectric cylinders buried in a slab medium,
illuminated by TE waves, has been proposed. By properly
arranging the direction of various unrelated waves, the
difficulty of ill-posedness and nonlinearity is avoided. Thus,
the permittivity distribution can be obtained by simple matrix
operations. The moment method has been used to transform a
set of integral equations into matrix form. Then these matrix
equations are solved by the unrelated illumination method.
Numerical simulation for imaging the permittivity distribution
of an inhomogeneous dielectric cylinder buried in a slab
medium has been carried out and good reconstruction has been
obtained even in the presence of Gaussian noise in measured
data. This algorithm is very effective and efficient, since no
iteration is required.
