A study on removal of Toluidine blue dye from aqueous solution by adsorption onto Neem leaf powder

Himanshu Patel and R. T. Vashi

Abstract—Adsorption of Toluidine blue dye from aqueous solutions onto Neem Leaf Powder (NLP) has been investigated. The surface characterization of this natural material was examined by Particle size analysis, Scanning Electron Microscopy (SEM), Fourier Transform Infrared (FTIR) spectroscopy and X-Ray Diffraction (XRD). The effects of process parameters such as initial concentration, pH, temperature and contact duration on the adsorption capacities have been evaluated, in which pH has been found to be most effective parameter among all. The data were analyzed using the Langmuir and Freundlich for explaining the equilibrium characteristics of adsorption. And kinetic models like pseudo first order, second-order model and Elovich equation were utilized to describe the kinetic data. The experimental data were well fitted with Langmuir adsorption isotherm model and pseudo second order kinetic model. The thermodynamic parameters, such as Free energy of adsorption ($\Delta G^\circ$), enthalpy change ($\Delta H^\circ$) and entropy change ($\Delta S^\circ$) were also determined and evaluated.

I. INTRODUCTION

The textile industry is confronted with serious environmental problems associated with its immense wastewater discharge, substantial pollution load, extremely high salinity, and alkaline, heavily colored effluent [1]. Dyes have usually a synthetic origin and complex aromatic molecular structures which make them more stable and more difficult to biodegrade. Degradation of dyes is typically a slow process [2]. The removal of color is needed to be considered in the disposal of textile wastewater due to aesthetic deterioration as well as the obstruction of penetration of dissolved oxygen into water bodies, which seriously affects aquatic life. Besides, the dye precursors and degradation products are proven carcinogenic and mutagenic in nature [3].

Most discharged textile wastewater is contributed mainly by scouring, bleaching, dyeing and finishing textiles [4]. These discharged textile wastewater contain very low neutral suspended solids. Chemical and biological methods have been employed for color removal from textile effluents. The former has not been very successful due to the essential non-biodegradable nature of most of the dyes [5]. The adsorption process is one of the most efficient methods of removing pollutants from wastewater. Also, the adsorption process provides an attractive alternative treatment, especially if the adsorbent is inexpensive and readily available. Data available that various type of adsorbent material available such as activated carbons [6], sawdust [7], alumite [8], fly ash [9], zeolite [10], sepiolite [11] which can be utilized to removal dye from aqueous solution. Also, some variables like agitator speed, temperature, pretreatment, adsorption capacity, adsorption size, particle size, bed height, EBET, adsorption type, source of carbon materials, type of contact, decide regeneration/ disposal, cyclic adsorption process (pH swing cycle), conductive adsorbent and adsorbate and also, carbon refining are helpful to make the sorption process affordable [12].

Toluidine Blue color (TBC), a phenothiazine type dye, has been widely used for different purposes in several fields such as medicine science, textile industry and biotechnology. It can be used as mediator for various chemical or biochemical reactions, colorant for cloth, photosensitizer for determining the actions of photoactivated microorganism and labelling agent for identifying organisms [13, 14]. Previously removal and adsorption kinetics of cationic dye, Toluidine Blue O, from aqueous solution using Turkish zeolite [15] and TBC using gypsum [16] was studied. Also, Neem (Azadirachta indica) leaf powder has been used to remove chromium (Cr) removal from aqueous solution [17] and color [18].

The present investigation deals with the preparation and characterization of natural material, Neem (Azadirachta indica) leaf powder and to study the adsorption capacity of NLP for Toluidine Blue dye from aqueous solution. The effect of initial concentration, pH, temperature and contact duration on the rate and the extent of adsorption were also examined. The Langmuir and Freundlich isotherm models were applied for their applicability. The pseudo and Elovich kinetic models were used to identify the possible mechanisms of such adsorption process. The thermodynamic analysis was also conducted to verify the nature of adsorption.
II. METHODS AND MATERIALS

A. Adsorbent

The neem belongs to the meliaceae family and is native to Indian sub-continent. Its seeds and leaves have been in use since ancient times to treat a number of human ailments and also as a household pesticide. The trees are also known as an air purifier and easily available in Indian region. The medicinal and gemicidal properties of the neem tree have been put to use in a variety of applications. The mature neem leaves used in the present investigation were collected from the trees in Navaug Science College, Surat, Gujarat. They were washed thrice with water to remove dust and water soluble impurities and were dried until the leaves become crisp. The dried leaves were crushed and powdered and further washed with distilled water till the washings were free of color and turbidity. Then the neem leaf powder was dried in an oven at 60 ± 2°C and placed in desiccator for the adsorption studies. The particle size of NLP was examined by Sympatic, Germany (Model: Helos-BF). The FTIR spectrophotometer (SHIMADZU, Japan: Model: 8400S) was used to analyze the functional group of adsorbent at wavelength 400-4000 cm\(^{-1}\). The XRD patterns of adsorbent were determined with an automated Philips, Heolant (Model: Xpert MPD) instrument using Cu Ka radiation at 40 kV and 40 mA over the range (20) of 5–70°. SEM image were taken using instrument, JEOL, Japan (Model: XL-30 JSM-S610LV).

B. Adsorbate

The TBC (C.I. number 52040) used in this study was procured from Merck Inc., Thailand. The empirical formula C\(_{12}\)H\(_{18}\)N\(_2\)SCI and formula weight 305.84 g/mol. The structure formula mentioned in figure 1.

![Fig. 1 Structure of TBC](image)

C. Experimental Procedure

The experiments were carried out as shown table maintaining adsorption dose of 3.0 g/l and temperatures of 313 to 363 K.

Briefly, 20 ml of the aqueous solution containing required amount of dye is treated with adsorbent in a 250 ml conical flask by shaking at 160 rpm on orbital shaker at requisite temperature, time duration and pH. The sample was allowed to settle down and then it was filtered through a Whatman filter paper No 1.

The concentration of the dye was measured by a spectrophotometer (ELICO SL 164 Double Beam UV-VIS Spectrophotometer) at \(\lambda_{\text{max}} = 622\) nm and quantity of dye adsorbed, \(q_e\) (g/g) by the NLP was calculated using the following formula:

\[
q_e = \frac{(C_o - C_e)}{W} \cdot V
\]

(1)

Where, \(C_o\) and \(C_e\) are the initial and equilibrium time solution concentrations of the dye (mg/l), respectively, \(V\) the volume of the solution (l) and \(W\) the weight of the NLP used (g).

The all solutions of TBC and others purposes were prepared by distilled water. 0.1 N NaOH and 0.1 N HCl used for adjustment of pH were analytical grade and purchased from Qualigens. All other chemicals used were of analytical reagent grade.

D. Adsorption isotherm

The equilibrium of sorption is one of important physico-chemical aspects for the evaluation of the sorption process as a unit operation. Sorption isotherm is the relationship between the sorbate in the liquid phase and the sorbate sorbed on the surface of the sorbent at equilibrium at constant temperature. The distribution of dye molecules between the liquid phase and the sorbent is a measure of the position of equilibrium in the sorption process and can be generally expressed by the two well known models viz., Freundlich, and Langmuir isotherm. The Freundlich isotherm can be efficient on multilayer and also, heterogeneous surface and is expressed by the following equation.

\[
q_e = K_f C_e^{1/n} \quad \text{or} \quad \log q_e = \log K_f + \frac{1}{n} \log C_e
\]

(2)

Where, \(q_e\) and \(C_e\) is the amount of adsorbed adsorbate per unit weight of adsorbent and unadsorbed adsorbate concentration in solution at equilibrium, respectively and \(K_f\) and \(1/n\) are Freundlich constant characteristics of the system, which are determined from the log \(q_e\) vs. \(\log C_e\).

Also, Langmuir adsorption is useful for predicting adsorption capacities and also interpreting into mass transfer relationship. The isotherm can be written as follows:

\[
\frac{C_e}{q_e} = \frac{1}{Q_{\text{max}}} + \frac{(b/Q_{\text{max}}) C_e}{(1/Q_{\text{max}})} \quad \text{or} \quad \frac{1}{q_e} = \frac{1}{Q_{\text{max}}} \frac{(1/C_e)}{(1/C_e) + (b/Q_{\text{max}})}
\]

(3)

Where, \(Q_{\text{max}}\) and \(b\) were the Langmuir constants, which measures of monolayer (maximum) adsorption capacity (in mg/g) and energy of adsorption (in g/l) respectively. The Langmuir parameters were obtained from the linear correlations between the values of \(1/q_e\) and \(1/C_e\) [19].
E. Adsorption Kinetics

The chemical kinetic describes reaction pathways, along times to reach the equilibrium whereas chemical equilibrium gives no information about pathways and reaction rates. Adsorption kinetics show large dependence on the physical and/or chemical characteristics of the adsorbent material, and adsorbate species which also influence the adsorption mechanism. In order to investigate the mechanism of adsorption such as chemical reaction, diffusion control and mass transfer, three kinetic models have been used at different experimental conditions for adsorption processes.

The pseudo first-order equation of Lagergren is given by

\[ \ln(q_t - q_e) = \ln q_e - k_1t \]  

(4)

Where \( q_t \) and \( q_e \) are the amounts of TBC adsorbed at time \( t \) and equilibrium (mg/g), respectively, and \( k_1 \) is the pseudo first-order rate constant for the adsorption process (1/min). The linear graph of \( \ln (q_t - q_e) \) vs. \( t \) shows the applicability of first order kinetic.

Also, the pseudo second-order chemisorption kinetic rate equation 5 is expressed as

\[ \frac{t}{q_t} = \frac{1}{k_2q_e^2} + \frac{1}{q_e}t \]  

(5)

Where \( k_2 \) is the equilibrium rate constant of pseudo second order equation (g/mg min). The linearity of \( t/q_t \) vs \( t \) suggests that pseudo second order kinetic is the fitted with practical data.

The Elovic equation was firstly used in the kinetics of chemisorption of gases on solids, it has been successfully applied for the adsorption of solutes from a liquid solution. The Elovic equation is given as follows:

\[ q_t = \frac{1}{\alpha \ln (\alpha \beta) + 1/\beta \ln t} \]  

(6)

Where \( \alpha \) (mg/g min) is the initial sorption rate and the parameter \( \beta \) (g/mg) is related to the extent of surface coverage and activation energy for chemisorption. The linear graph of \( q_t \) vs. \( \ln t \) shows the applicability of Elovic kinetic [18].

F. Thermodynamic Study:

Thermodynamic parameters Gibbs free energy \((\Delta G^\circ)\), change in enthalpy and \((\Delta H^\circ)\) change in entropy \((\Delta S^\circ)\) were obtained from the experiments carried out at different temperatures. The free energy of adsorption \((\Delta G^\circ)\) can be related with Langmuir adsorption constant [20] by the following equation:

\[ \Delta G = -RT \ln K_L \text{ Or} \]

\[ \ln K_L = -\Delta G^\circ/RT = (\Delta S^\circ/RT) - (\Delta H^\circ/RT) \]  

(7)

Thus, a plot of \( \ln K_L \) versus \( 1/T \) should be a straight line. \( \Delta H^\circ \) and \( \Delta S^\circ \) values were obtained from the slope and intercept of this plot, respectively.

III. RESULTS AND DISCUSSIONS

A. Surface Characteristic of Adsorbent

The average particle size of NLP is 70-90 \( \mu \)m, which is generally used as adsorbent materials to remove different types of contamination and dyes [8, 21]. FTIR spectrogram of NLP is shown in figure 2, which can interpreted as large stretching between 3000 – 3500 cm\(^{-1}\) due to carboxylic acid and amino group, band at 2926 cm\(^{-1}\) is due to the aliphatic CH stretching of methyl group and a sharp band around 1734 and 1653 cm\(^{-1}\) is due to stretching frequency of C=O and bending N-H groups respectively. Bands around 1365 and 1240 cm\(^{-1}\) are due to phenolic OH and -SO_2H groups respectively. The FTIR of some adsorbent shows the related stretching having large adsorption capacities of 80 to 90% [10, 22].

![Fig. 2 FT-IR spectra of NLP](image)

The XRD graph of NLP (figure 3) shows that the material is partially amorphous, which effectively used as adsorbent [12, 23].

![Fig. 3 XRD spectra of NLP](image)

Scanning Electron Microscopic images of NLP at lower and higher magnifications were shown in figure 2 (B) - 1 and 2 respectively, in which highly porous surface morphology of NLP was observed.
B. Effect of pH

The effect of pH (1 to 11) on adsorption of TBC by partially amorphous NLP at various temperatures at contact duration 4 hrs and initial dye concentration of 0.005 mg/l mentioned in Figure 3 (A). It was found that the color is stable or minor increase in the initial pH range 1 to 5, but color reduction increases in aqueous solution as pH increases from 7 to 11.

C. Effect of initial concentration

Figure 6 depicted effect of initial concentration of TBC onto NLP having particle size 70-90 microns, in which the amount of the TBC adsorbed onto adsorbent increases with an increase in the initial concentration of dye solution varying from 0.0001 to 0.0009 mg/l for 0.1 to 0.9 mg/l dosage of adsorbent. This is due to the increase in the driving force of the concentration gradient with the higher initial dye concentration [24].

D. Effect of contact duration

The influence of contact duration on adsorption of TBC was presented in figure 7, in which amount of adsorption of dye are continuously increasing with increasing contact durations (from 30 to 480 min). That is probably due to the larger surface area of adsorbent at the beginning for the adsorption of TBC. As the surface adsorption sites become exhausted, the uptake rate is controlled by the rate at which the adsorbate is transported from the exterior to the interior sites of the adsorbent particles [25].

E. Adsorption isotherm

The non-linear graph of Freundlich and Langmuir isotherm models using NLP at different temperatures (310, 320 and 330 K) was depicted in above figure 8. It represented that the data were fitted to both isotherm. The parameters like Freundlich constants (K_F and n), Langmuir constants (Q_max and K_L) and their linear correlation coefficient (r^2) were mentioned in table II. Entire temperatures range studied with a good
linear correlation coefficient, showing that data correctly fit than Langmuir isotherm than correlation coefficient, showing that data correctly fit the Langmuir isotherm than Freundlich isotherm, proving monolayer and homogenous surface of adsorbent. The same pattern was observed for absorption of various types of dye onto adsorbents (26, 27). Maximum adsorption capacities related to Langmuir isotherm were found to be 157.4, 165.3 and 186.6 mg/g at 310, 320 and 330 K respectively. Previously, adsorption of TBC onto Turkish Zeolite was conducted by Alpat and maximum adsorption capacity was found to be 55 mg/g [15].

**F. Adsorption kinetic**

Table 3 described kinetic parameters for the adsorption of TBC onto NLP, in which the correlation coefficients ($r^2$) for the linear plots of pseudo-second order plots are better than the pseudo-first order reaction plots and Elovich equation. This shows that the pseudo-second order kinetic model explains the sorption in better way. The pseudo-second order model is based on the assumption that the rate determining step may be a chemical sorption involving valence forces through sharing or exchange of electrons between sorbent and sorbate [25].

**G. Thermodynamic study:**

The thermodynamic parameters such as Free energy of adsorption ($\Delta G^0$), enthalpy change ($\Delta H^0$) and entropy change ($\Delta S^0$) were tabulated in table no. 2. The negative values of $\Delta G^0$ were -1.96, -2.64, -2.97, -3.62, -3.99 and -4.65 at 300, 310, 320, 330, 340 and 350 K respectively, which is indicates that adsorption process is spontaneous. The value of $\Delta H^0$ was -52.867 kJ/mol, which was in the range of chemisorption. The negative value of $\Delta H^0$ also indicated that the adsorption process is exothermic. Further, negative values of $\Delta S^0$ suggested that the TBC molecules are more regularly arranged (decrease in randomness) on the adsorbent surface. The same results indicated in reference literature [20].

**IV. Conclusion**

The NLP has shown to use for adsorption capacities compared to many other available non-conventional adsorbents. The various process parameters like pH, initial concentration, adsorbent dosage and contact duration were investigated in this study, in which pH is to found effective for adsorption of TBC onto NLP. Equilibrium and kinetic studies were conducted for the adsorption of TBC from aqueous solutions onto NLP. The equilibrium data have been analyzed using Langmuir and Freundlich isotherms. The characteristic parameters for each isotherm and related correlation coefficients have been determined. The Freundlich isotherm was demonstrated to provide the best correlation for the adsorption of TBC onto NLP. At the same way, correlation coefficients were obtained for kinetic models like, pseudo first-order, second-order model and Elovich equation. The pseudo second-order model is more fitted than others. The thermodynamic results shows that adsorption process of TBC onto NLP was exothermic, chemisorption and spontaneous.
