Beam and Diffuse Solar Energy in Zarqa City

Ali M. Jawarneh

Abstract—Beam and diffuse radiation data are extracted analytically from previous measured data on a horizontal surface in Zarqa city. Moreover, radiation data on a tilted surfaces with different slopes have been derived and analyzed. These data are consisting of beam contribution, diffuse contribution, and ground-reflected contribution radiation. Hourly radiation data for horizontal surface possess the highest radiation values on June, and then the values decay as the slope increases and the sharp decreasing happened for vertical surface. The beam radiation on a horizontal surface owns the highest values comparing to diffuse radiation for all days of June. The daily total radiation on the tilted surface decreases with slopes. The beam radiation data also decays with slopes especially for vertical surface. Diffuse radiation slightly decreases with slopes with sharp decreases for vertical surface. The ground-reflected radiation grows with slopes especially for vertical surface. It’s clear that in June the highest harvesting of solar energy occurred for horizontal surface, then the harvesting decreases as the slope increases.

Keywords—Beam and Diffuse Radiation, Zarqa City

I. INTRODUCTION

DUE to sharp increase in conventional energy prices and environmental effects, solar energy is being seriously considered for satisfying part of the energy demand in Jordan. Jordan like other developing countries in general has to meet the energy challenges for achieving the requirements of the government strategy for a comprehensive and sustainable social and economic development. The lack of commercial energy resources in Jordan and dependence on crude oil and oil products imports, high population growth rate, an expected continuous high energy consumption growth rate of about (3%) / year and (6%) for the electricity consumption, all these yearly costs make the energy bill a big burden on the national economy. Part of the solution to this problem is to utilize Jordan’s renewable energy resources like solar energy. According to the energy sector’s strategy of Jordan, it is planned that the renewable energy contribution will reach 3% of the overall energy mixture until the year 2015 [1]. Zarqa is a city in Jordan located to the north-east of Amman. It is the capital of Zarqa Governorate. Zarqa city lies at latitude of 32° 5' N and longitude of 36° 7' E with elevation of 555 m. Zarqa can be described as having a desert climate.

Several studies have been showed that the solar energy are promising in Jordan [2]-[4]. Jordan is one of the sun belt countries according to the international classification since the average annual solar radiation per day is (3.8) Kwh/m² in winter to more than (8) Kwh/m² in summer. The yearly global solar radiation in Jordan ranges from (1700) Kwh/m² in Jordan Valley to more than (2250) Kwh/m² for Hill area which facilitates building investment projects utilizing solar energy for the generation of electricity [5], [6]. Fine contribution to study the visibility of some applications that driven by solar energy in Jordan had been done by [7]-[9].

The availability of solar data (beam, diffuse, and ground reflected radiation) either on a horizontal or tilted surfaces may be encouraging the existing energy units to seek alternatives such as combined solar-thermal energy or hybrid system.

Since the measurements of total radiation (beam plus diffuse) were done on a horizontal surface as explained in previous work by Jawarneh and Al-Shyyab [10], then beam and diffuse radiation data for a horizontal surfaces can be deduced separately from the available data on the horizontal surfaces. Moreover, beam contribution, diffuse contribution, and ground-reflected contribution radiation data can also be extracted for the tilted surfaces. Measurements of solar radiation on inclined planes are important in determining the input to solar collectors, PV cells, and passive heating and cooling systems.

The main objective of this current paper is to introduce a solar radiation data in Zarqa city and assess the characteristics of the solar radiation that will include the beam, and diffuse radiation on a horizontal surface. In addition, the beam, diffuse and ground–reflected contribution on the tilted surface will be introduced and assessed.

II. DATA COLLECTION

The solar radiation data on June 2009 was measured using Pyranometer which measures the global radiation on horizontal surfaces. It is mounted on the roof of the engineering college in Hashemite University. It contains carefully calibrated thermolectric elements fitted under a glass cover, which is open to the whole vault of the sky. A voltage proportional to the total incident light energy is produced and then recorded electronically. Pyranometer measurements are recorded simply as total energy incident on the horizontal surface (beam plus diffuse). Data are recorded every 5 min and then averaged on hourly, daily, and monthly basis. The sensor is photodiode detector, the spectral response from 0.4 to 1.1 microns, the sensivity is 100 mV/1000 W/m², and the accuracy is ±5%.

III. METHODS OF ANALYSIS

(a) Horizontal Surfaces

We should refer that the following equations are taken from Duffie and Beckman [11]. The declination can be found from:

$$\delta = 23.45 \sin\left(360 \frac{284 + n}{365}\right)$$

(1)

where n is day of the year counted from 1st January. The hour angle $\omega$ was calculated as:

$$\omega = [\text{solar time} - 12:00] (\text{in hrs}) \times 15^\circ$$

(2)

The solar time is defined as:

$$\text{solar time} - \text{standard time} = -4(L_e - L_{\text{loc}}) + E$$

(3)

where $L_e$ is the standard meridian for the local time zone (for Jordan $L_e = 30^\circ E$), and $L_{\text{loc}}$ is the longitude of the location (for Zarqa city, $L_{\text{loc}} = 36^\circ E$). The solar azimuth angle $\gamma$ can be estimated according to the following formula,
The daily extraterrrestrial radiation \( H_0 \) on a horizontal surface at any time is given by:

\[
H_0 = G_o \left( 1 + 0.033 \cos \frac{360 \delta}{365} \right) \cos \theta_
u
\]  

(8)

Extraterrrestrial radiation \( G_o \) on a horizontal surface is estimated as:

\[
G_o = \frac{12 \times 3600}{\pi} G_{sc} \left( 1 + 0.033 \cos \frac{360n}{365} \right) \times \left[ \cos \phi \cos \delta \sin \omega_0 - \sin \omega_1 \right] + \frac{\pi (\omega_1 - \omega_0)}{180} \sin \phi \sin \delta
\]  

(9)

The daily extraterrrestrial radiation \( H_o \) on a horizontal surface is given by:

\[
H_o = \frac{24 \times 3600}{\pi} G_{sc} \left( 1 + 0.033 \cos \frac{360n}{365} \right) \times \left( \cos \phi \cos \delta \sin \omega_1 + \frac{\pi \omega_0}{180} \sin \phi \sin \delta \right)
\]  

(10)

Beam and diffuse components of hourly radiation can be estimated as:

\[
I = \begin{cases} 
1 - 0.09 k_T & \text{for } k_T \leq 0.22 \\
0.9511 - 0.1604 k_T + 4.388 k_T^2 & \text{for } 0.22 < k_T \leq 0.8 \\
-16.638 k_T + 12.33 k_T^2 & \text{for } k_T > 0.8
\end{cases}
\]  

(11)

where \( k_T \) is an hourly clearness index and is given by:

\[
k_T = \frac{I}{I_o}
\]  

(12)

The day’s total radiation on a horizontal surface in HU for June are measured, so the fraction and amount of beam and diffuse radiations can be calculated by:

\[
s_{max} = \frac{1}{\sin \theta} \left( \frac{\omega_0 - \omega_1}{\pi} \right) \sin \phi \sin \delta
\]  

\[
T_{max} = \frac{I_o}{\sin \theta} \left( \frac{\omega_0 - \omega_1}{\pi} \right) \sin \phi \sin \delta
\]

where \( \omega_0 \) and \( \omega_1 \) are measured, so the fraction and amount of beam and diffuse for period between two hours angle \( \omega_0 \) and \( \omega_1 \) can be calculated by:

\[
s_{max} = \frac{1}{\sin \theta} \left( \frac{\omega_0 - \omega_1}{\pi} \right) \sin \phi \sin \delta
\]  

\[
T_{max} = \frac{I_o}{\sin \theta} \left( \frac{\omega_0 - \omega_1}{\pi} \right) \sin \phi \sin \delta
\]

The sunset hour angle \( \omega_s \) is estimated as:

\[
\omega_s = -\tan \phi \tan \delta
\]  

(7)

The hourly diffuse radiation is assumed to be anisotropic. It can be written from the anisotropic sky model as:

\[
I_b = (I_i + I_A) R_b + I_i (1 - A) \frac{1+ \cos \beta}{2} \left[ 1 + f \sin \frac{\beta}{2} \right] + \frac{1 - \cos \beta}{2}
\]

(18)

where, \( (1+\cos \beta)/2 \) is the view factor to the sky, \( (1-\cos \beta)/2 \) is the view factor to the ground, \( R_b \) is the reflectance of the ground and it is assumed to be 0.3 due to desert climate. The first term in previous equation represents the beam contribution, the second term represents the diffuse contribution, and the last term represent the ground-reflected contribution. An anisotropy index \( A \) which is a function of the transmittance of the atmosphere for beam radiation, \( A = e_b I_o / l \), and \( f \) is given by \( f = \sqrt{I_i/I_o} \).

The geometric factor \( R_b \) is the ratio of beam radiation on the tilted surface to that on a horizontal surface at any time, can be calculated as:

\[
R_b = \frac{G_{b,T}}{G_b} = \frac{I_{b,T}}{I_b} = \frac{\cos \theta}{\cos \theta_i}
\]  

(19)
The daily radiation on an unshaded tilted surface, if the diffuse and ground radiation are each assumed to be isentropic, can be expressed as:

\[ H_d = H(1 - \frac{1}{H})R_h + H_d\frac{1 + \cos \beta}{2} + H_p\frac{1 - \cos \beta}{2} \]  
(20)

where \( R_h \) is the ratio of the daily beam radiation on the tilted surface to that on the horizontal surface:

\[ R_h = \frac{H_{st}}{H} \]

\[ = \frac{\cos(\phi - \beta) \cos \delta \sin \omega s_1 \sin(\phi - \beta) \sin \delta}{\cos \phi \cos \delta \sin \omega + (\pi/180) \omega \sin \phi \sin \delta} \]

where \( \omega_s \) is the sunset hour angle for the tilted surface for the particular day is given by

\[ \omega_s = \min \left[ \frac{\cos^{-1}(\tan \phi \tan \delta)}{\cos^{-1}(\tan(\phi - \beta) \tan \delta)} \right] \]

The monthly average daily radiation on an unshaded tilted surface, if the diffuse and ground radiation are each assumed to be isentropic, can be expressed as:

\[ \Pi_d = \Pi(1 - \frac{1}{\Pi})R_h + \Pi_d\frac{1 + \cos \beta}{2} + \Pi_p\frac{1 - \cos \beta}{2} \]  
(23)

Where \( R_h \) is the ratio of the average daily beam radiation on the tilted surface to that on the horizontal surface for the month:

\[ R_h = \frac{\Pi_{st}}{\Pi} \]

\[ = \frac{\cos(\phi - \beta) \cos \delta \sin \omega s_1 \sin(\phi - \beta) \sin \delta}{\cos \phi \cos \delta \sin \omega + (\pi/180) \omega \sin \phi \sin \delta} \]

where \( \omega_s \) is the sunset hour angle for the tilted surface for the mean day of the month which is given by

\[ \omega_s = \min \left[ \frac{\cos^{-1}(\tan \phi \tan \delta)}{\cos^{-1}(\tan(\phi - \beta) \tan \delta)} \right] \]

IV. RESULTS AND DISCUSSION

The objective of previous work by Jawarneh [10] was to introduce four types of solar radiation data on a horizontal surface. Those are irradiance \( G \) (W/m²), hourly radiation I (MJ/m²), daily radiation H (MJ/m²), and monthly average daily radiation \( H' \) (MJ/m²). In extension to previous work we will extract the beam and diffuse radiation from the total radiation on a horizontal surface (\( \beta = 0^\circ \)), then we will introduce the radiation data on a tilted surfaces with different slopes. These data will consist of of beam, diffuse, and ground-reflected radiation.

We should refer here that June 2009 was selected for present calculations. June 11 is selected that concern monthly average daily radiation. Moreover, the slopes of \( \beta = 20^\circ, 32^\circ, 45^\circ, \) and \( 90^\circ \) for tilted surface were selected and faced south with surface azimuth angle \( \phi = 0^\circ \) also was selected.

Hourly radiation data for horizontal surface I and tilted surfaces \( \Pi \) for June 11 are given in Fig.1. The comparison is made for different slopes (\( \beta = 0^\circ, 20^\circ, 32^\circ, 45^\circ, \) and \( 90^\circ \)). Slope with \( \beta = 0^\circ \) is referring to a horizontal surface and it’s possess the highest values. The values then decay as the slope increases and the sharp decreasing happened for vertical surface (\( \beta = 90^\circ \)).

Hourly radiation components on a horizontal surface I (\( \beta = 0^\circ \)) with it’s components (beam, \( I_b \) and diffuse, \( I_d \) ) and hourly radiation components on a tilted surface \( \Pi \) with it’s components (beam contribution, \( (I_b+H_2A_2)R_h \), diffuse contribution, \( I_d(1-A_2)(1+\cos \beta)/2[1+\sin^2(\beta/2)] \), and ground-reflected contribution, \( I_p(1-\cos \beta)/2 \) on a tilted Surface with a slope of \( \beta = 20^\circ \) for June 11 is given in Fig.2.

Daily total radiation H with it’s components of it’s beam \( H_b \) and it’s diffuse \( H_d \) radiation on a Horizontal Surface for June is shown in Fig. 3. The beam radiation owns the highest values comparing to diffuse radiation for all days of June.

Fig.4 to Fig.7 show daily total radiation on a tilted surface \( \Pi \) with it’s components of beam contribution \( H(1-H_2/H)R_h \), diffuse contribution \( H_d(1+\cos \beta)/2 \) and ground-reflected contribution \( I_p(1-\cos \beta)/2 \) for different slopes starting from slope of \( \beta = 0^\circ \) to slope of \( \beta = 90^\circ \). The daily total radiation on the tilted surface \( \Pi \) decreases with slopes. The beam radiation data also decays with slopes especially for vertical surface \( \beta = 90^\circ \). Diffuse radiation slightly decreases with slopes with sharp decreases for vertical surface. The ground-reflected radiation grows with slopes especially for vertical surface where the total radiation is coming mainly from the ground-reflected radiation.

Fig.8 compared the daily total radiation between the horizontal surface (\( \beta = 0^\circ \)) and inclined surfaces (\( \beta = 0^\circ, 20^\circ, 32^\circ, 45^\circ, \) and \( 90^\circ \)). It’s clear that in June the highest harvesting of solar energy occurred for horizontal surface (\( \beta = 0^\circ \)), then the harvesting decreases as the slope increases.

Table I shows the monthly average daily total radiation on a horizontal surface \( H' \) and on inclined surfaces \( H' \). June 11 is the monthly average day. The beam and diffuse contribution decrease with slopes while the ground-reflected contribution grows up with slopes.

### TABLE I

| MONTHLY AVERAGE DAILY RADIATION AT AN AVERAGE DAY OF 11 OF JUNE |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| $\beta$ (deg)  | $H_{1}$ (W/m²) | $H_{2}$ (W/m²) | $H_{3}$ (W/m²) | $H_{4}$ (W/m²) | $H_{5}$ (W/m²) | $H_{6}$ (W/m²) | $H_{7}$ (W/m²) |
| 0°              | -               | -               | -               | 24.65           | 6.33            | 30.98           |                 |
| 20°             | 22.42           | 6.14            | 0.28            | 28.84           | -               | -               |                 |
| 32°             | 20              | 5.85            | 0.71            | 26.55           | -               | -               |                 |
| 45°             | 16.57           | 5.4             | 1.36            | 23.33           | -               | 5.4             |                 |
| 90°             | 1.82            | 3.16            | 4.65            | 9.63            | -               | -               |                 |

### V. CONCLUSIONS

Beam, diffuse and ground-reflected radiation data is extracted analytically and analyzed from previous measured data on a horizontal surface. In June the highest harvesting of solar energy occurred for horizontal surface, then the harvesting decreases as the slope increases. The ground-reflected radiation grows with slopes especially for vertical surface.
