Determination and Preconcentration of Iron (II) in Aqueous Solution with Amberlite XAD-4 Functionalized with 1-amino-2-naphthole by Flame Atomic Absorption Spectrometry

Homayon Ahmad Panahi, Mahshid Nikpour Nezhati, Faranak Mahmoudi, Elham Moniri, Meghdad Karimi

Abstract—A new chelating resin is prepared by coupling Amberlite XAD-4 with 1-amino-2-naphthole through an azo spacer. The resulting sorbent has been characterized by FT-IR, elemental analysis and thermogravimetric analysis (TGA) and studied for preconcentrating of Fe (II) using flame atomic absorption spectrometry (FAAS) for metal monitoring. The optimum pH value for sorption of the iron ions was 6.5. The resin was subjected to evaluation through batch binding of mentioned metal ion. Quantitative desorption occurs instantaneously with 0.5 M HNO₃. The sorption capacity was found 4.1 mmol.g⁻¹ of resin for Fe (II) in the aqueous solution. The chelating resin can be reused for 10 cycles of sorption-desorption without any significant change in sorption capacity. A recovery of 97% was obtained the metal ions with 0.5 M HNO₃ as eluting agent. The method was applied for metal ions determination from industrial waste water sample.

Keywords—Amberlite XAD-4; Iron (II); Flame atomic absorption; Chelator; 1-amino-2-naphthole

I. INTRODUCTION

The direct determination of trace elements in real samples is a difficult task. The main restrictions come from the complexity of the matrix and the extremely low concentrations of analytes in those samples, which are often below the detection limits of available techniques [1, 2]. Thus, highly sensitive and selective techniques are required. Although the sensitive and accurate determination of trace elements by some instrumental techniques including inductively coupled plasma mass spectrometry, graphite furnace atomic absorption spectrometry [3, 4] is preferred for trace element determination due to its cheap cost and simplicity. However, the determinations of elements at μgL⁻¹ concentration level by flame atomic absorption spectrometry are not possible. To solve this problem, preconcentration-separation procedures have been proposed.

II. EXPERIMENTAL

Reagents

Amberlite XAD-4 resin (surface area 745 m²/g, pore diameter 5 nm and bead size 20-60 mesh) was obtained form serva. 1-amino-2-naphthole was synthesized in Ethanol 51. The metal ion solution was prepared by dissolving following metal salts: Fe (NO₃)₂.4H₂O. The following buffers were used to control the pH of the solutions: Hydrogen disodium phosphate (pH=7-9), Sodium Hydroxide-Acetic acid (pH=5), Acetic acid (pH=3-4). CH₃COOH, NaH₂PO₄, Na₂HPO₄, CoCl₂.6H₂O, SnCl₂, HCl, H₂SO₄, HNO₃, NaNO₂, NaOH, β-Naphthole, Aniline, Iodide-Starch Paper were products of Merck (Darmstadt, Germany).

Instruments

A flame atomic absorption spectrometer of the Shimadzu, model AA-680, equipped with air-acetylene flame (air and acetylene flow rate: 8 and 1.7 L.min⁻¹, respectively) was used for measuring the concentration of metal ions. The pH measurements were made with Metrohm model 744 (Switzerland). IR spectra were recorded on a FT-IR spectrometer Jasco / FT-IR-410 by KBr pellet method. Elemental analysis was carried out on an elemental analyzer from Thermo-Finnigan (Milan, Italy) model Flash EA. TGA analysis was carried out by using TGA-50H (Shimadzu, Japan).

Synthesis of XAD-4- (1-amino-2-naphthole)

Amberlite XAD-4 bead (5g) were treated with 10 cm³ of concentrated HNO₃ and 25 cm³ of concentrated H₂SO₄ and the
mixture stirred at 60ºC for 1h on an oil bath. Thereafter, the reaction mixture was poured into an ice water mixture. The nitrated resin was filtered, washed repeatedly with water until free from acid and thereafter treated with a reducing mixture of 40g of SnCl₂, 45 cm³ of concentrated HCl and 50 cm³ of ethanol. The mixture was refluxed for 12h at 90ºC. The solid precipitate was filtered and washed with 1mol/dm³ HCl and 1mol/dm³ NaNO₂ (added in small aliquots of 1cm³) until the reaction mixture showed a permanent dark blue color with starch-iodide paper. The diazotized resin was filtered, washed with ice-cold water and react with 1-amino-2-naphthole 0.03 mol in 200 cm³ of 10% NaOH solution. The resulting colored beads were filtered, washed with water and dried in air.

The methodology used to synthesize modified XAD-4 resins is summarized in Fig. 1.

**Fig. 1 The methodology of synthesize of 1-amino-2-naphthole – Amberlite XAD-4**

**Batch method**

A sample solution (100ml) containing 0.1-30 µg.mL of Fe (II) was placed in glass stopper bottle after adjusting its pH to the optimum value. The modified Amberlite XAD-4 (0.1g) was added. The bottle was shaken for 5h. The resin was filtered and the metal ions were desorbed by shaking the resin beads with 10 mL HNO₃ 1M. The resin was filtered off and the filtrate was aspirated into FAAS.

**III. RESULTS AND DISCUSSION**

**Characterization of modified Amberlite IR Spectrum**

The IR spectrum of 1-amino-2-naphthole loaded Amberlite XAD-4 (Fig. 2) is compared with that of free Amberlite XAD-4 (Fig. 1). There are 4 additional bands at 1557, 1606, 1279 and 3415 cm⁻¹ which appear to originate due to modification of N-H (bending), N=N, C-N (bending) and O-H, NH₂ vibrations, respectively.

**Fig. 2 IR spectrum of a) Amberlite XAD-4 b) 1-amino-2-naphthole – Amberlite XAD-4**

**Elemental Analysis**

The instruction used in this study is reported in ThermoFinnigan elemental analyzer manual. Elements of C, H and N in the sample and standards in a column containing oxidant at 900 ºC were converted to CO₂, H₂O and N₂, respectively. They separated in a GC column containing molecular sieve and detected by a Thermal conductivity detector (TCD). The percentages of C, H and N in the sample were ascertained after drawing the calibration curve for standards and data processing for the sample.

The elemental analysis for Amberlite XAD-4 (1-Amino-2-Naphtole) (found: C, 75.85; H, 9.02; N: 4.11%, calculated for (C₈H₇)₆C₁₀N₃H₈O(H₂O)₆ : C, 77.67; H, 6.91; N, 4.68%) show that on an average one (1-amino-2-Naphtol) molecule is present in each 6 repeat unit of the polymer.

**Thermal Analysis**

TGA of the resins shows two-step weight loss up to 510 ºC. The weight loss up to 130ºC was due to the water molecules in the polymer. The major weight loss after 290ºC is due to the dissociation of chemically immobilized moiety and the polymeric matrix.

**Metal sorption as a function of pH**

The degree metal sorption at different pH values was determined by batch equilibration technique. A set of solutions (volume of each 50 mL) containing 0.3 µg.mL⁻¹ Fe (II) was taken. Their pH values were adjusted in range 3-9 with 0.01 M acetate and/or phosphate buffer solutions. The 0.1 g of 1-amino-2-naphthole loaded Amberlite XAD-4 was added to each solution and the mixture was shaken for 5 h. The optimum pH values for quantitative uptake of metal ions were ascertained by measuring the metal ions content (by FAAS) in
supernatant liquid and in the eluate obtained by desorbing the metal ion from resin with 0.5 M nitric acid (10 mL). The optimum pH range for the sorption Fe (II) is shown in figure 3. The maximum recovery was 97% at pH 6.

![Fig. 3](image)

**Stability and reusability of the resin**

The mentioned metal ions were sorbed and desorbed on 1g of the resin several times. It was found that sorption capacity of resin after 10 cycles of its equilibration with the metal ions, changes less than 5%. Therefore, repeated use of the resin is feasible. The resin cartridge after loading it with samples can be readily regenerated with 0.5 M HNO₃. The sorption capacity of the resin stored for more than 6 month under ambient conditions has been found to be practically unchanged.

**Total sorption capacity**

The 0.01g of resin beads were stirred for 5 h with 100 mL solution containing 30 μg.mL⁻¹ of Fe (II), at optimum pH. The metal ion concentration in the supernatant liquid was estimated by FAAS. The sorption capacity of the resin for each metal ion was ascertained from the difference between the metal ion concentrations in solution before and after the sorption. The saturated adsorption capacity of the resin for Fe (II) is 4.1 mmol.g⁻¹ of resin.

**Application of method**

Solid phase extraction with 1-amino-2-naphthole loaded Amberlite XAD-4 coupled with FAAS determination was applied to determine the Ni (II), Zn (II) and Fe (II) in plating waste water sample. The sample solution (100 mL) was taken in a glass stoppered bottle (250 mL), after adjusting its pH to the optimum value. The 0.5g of 1-amino-2-naphthole – Amberlite XAD-4 was added to the bottle and the mixture was shaken for 30 min. The resin was filtered and sorbed metal ion was eluted with 0.5 M HNO₃ (10 mL). The concentration of metal ion in the eluate was determined by a pre-standardized FAAS. The results are shown in Table 1. These results demonstrate the applicability of the procedure for Ni, Fe and Co determination in samples.

**IV. CONCLUSION**

A new resin was synthesized by coupling of Amberlite XAD-4 with 1-amino-2-naphthol. Amberlite XAD-4-1-amino-2-naphthole has a good potential for enrichment of trace amounts of Fe from large sample volumes. The synthesis of the resin is simple and economical. The resins can be applied over a wide pH range (3-9) for collection of trace metals. All the resins also present the advantage of high adsorption capacity, good reusability and high chemical stability. Preconcentration by this resin combine with FAAS can be applied to the determination of trace Fe (II), Zn (II) and Ni (II) ions in water and mineral reference sample with satisfactory results.
