Abstract—The Kinetics formation of labile Complex Ag (I) tetra (p-carboxyphenyl) porphyrin, was investigated at 25°C and I=0.1M (NaNO₃). By spectrophotometric titration, the composition ratio of the complex was established to be 2:1 (Ag : H₂TCPP). The equilibrium constant, K, was found to be \( \log_{10} 10^{-6.53} \). Binding of the first Ag (I) was found to be rate determining step with rate constant, \( k_1 = 4.67 \times 10^2 \). A plausible mechanism is discussed. We discus theoretically why Ag(I)TCPP is unstable.

Keywords—Kinetics, Silver, TCPP, Sitting-atop, Theoretical study

I. INTRODUCTION

THIS porphyrins lie at the focus of several different fields of research [1-3]. Porphyrins, being macrocyclic chelating ligands offer a convenient tool for studying the chemistry of unusual oxidation states of transition metals [4]. Porphyrins, work as anti poison drugs in the biological systems in our previous work Co(III) in TPPS porphyrin, scavenges cyanide by forming an extremely stable monocyano adduct. [5]. Metalloporphyrins control the decisive steps in various natural and technological processes, which often involve the reversible attachment of a molecular ligand to the central metal ion [6]. In the previous work, [N-Methyltetras (4-sulfonatophenyl)]porphinato] cobalt(II), -nickel(II), and -copper(II) [M⁶(N-Me)TSPP] have been prepared, The Ni derivative, moreover, produced MeNi⁶TSPP which was unstable and gave Ni⁶TSPP and methyl radical[7]. A kinetic study of the acid solvolysis reactions of divalent nickel, cobalt, zinc and copper complexes of N-methyl-tetra(4-sulfonatophenyl) porphyrin was done at 25°C in aqueous solution.

All reactions were first order in metalloporphyrin and first order in [H⁺]. Only the Zn and Cu derivatives had a second term proportional to [H⁺][Ac⁻]. Calculated formation constants of the uncatalyzed reactions were in the order Ni > Cu > Zn > Co > Cd. The results showed that kinetically N-alkylated metalloporphyrins require one less proton for acid solvolysis than do the corresponding metalloporphyrins[8]. Metalloporphyrins are kinetically inert complex. If, however, the ionic radius of the metal ions is too large to fit into cavity, they are located out of the ligand plane, distorting it and form sitting-atop complexes [9].

The SAT (sitting-atop) phenomena previously observed with TPyP, can be explained by 1. an unusual anion term in the rate law, 2. the strong increase in pK₃ and pK₄ upon increase in ionic strength, and 3. the lack of reactivity of mono- and dication forms toward metal ions [10]. A series of sulfonated water-soluble, phenyl-substituted porphyrins has been reported, containing halogen or alkyl groups in the ortho, di-ortho or para positions. While the para-substituted compounds exhibited monomer-dimer behaviour, all the ortho and di-ortho substituted porphyrins were monomeric in aqueous solution at 0.1 M ionic strength [11]. From the absorption spectra of porphyrins the Soret bands assigned to the S₂→S₁ transitions in the 380-440 nm range and the Q bands assigned S₀→S₂ are shown in the 500-700 nm range.

Simplified energy-level diagram of the frontier orbital of a porphyrin in free-base state (H₂P), in a regular (AlP) and in a SAT (HgP) metalloporphyrin are shown in Fig 1[9].

![Fig. 1 Simplified energy-level diagram of the frontier orbital of a porphyrin in free-base state H₂P, in a regular AlP and in a SAT HgP metalloporphyrin.](image)

Kinetics studies of formation of metalloporphyrin are discussed by other researchers [12-16]. Incorporation of Ag into other porphyrins are studied by Krishnamurthy and et all [17], but we studied on tetra (p-carboxyphenyl) porphyrin, (H₂TCPP) with Ag kinetically and discussed why Ag₂TCPP is unstable and stable form of the product is AgTCPP.
II. RELATED WORK

A. Experimental Section

Shimadzu UV/visible spectrophotometer and Durrum stopped flow apparatus thermostatted at 25±0.2 °C were used for kinetic studies. All kinetic studies were carried out in presence of buffer, pH=9 and I=0.1 M (NaNO₃). Plots of log (Aₜ–Aᵢ) vs. time were linear for over three half lives. The H₂TCPP was synthesized by the method of Adler, pyrrole with 4-carboxy benzaldehyde and propionic acid with 2 hour reflux. Stable Ag (II) porphyrins are synthesized by mixing a porphyrin solution with a Ag (I) salt such as nitrate. On mixing the two, the red porphyrin solution becomes green momentarily then slowly changes to red, often accompanied by a silver mirror. The green colour is result of acidate during the dissociation of H⁺ from pyrrole and the final red colour is due to Ag(II)porphyrin, formed as a result of disproportionation of Ag(I) ions in macrocycle.

Theoretical study of silver porphyrin is measured by Gaussian and Hyper programs. Spectrophotometric titration were carried out by placing 500 cm³ of porphyrin solution, containing 5.0 cm³ of stock porphyrin, 50.0 cm³ of 0.1 M buffer solution and 25 cm³ of 2.0 M NaNO₃ in a jacketed vessel. The solution was thermal equilibrated for 30 min. Different aliquots of 0.1 M AgNO₃ solution were added, employing a microburette. Before each addition, the spectrum of porphyrin sample was recorded. By retaining this sample, the total volume was maintained close to 500±50 cm³ allowing for silver nitrate.

III. RESULTS AND DISCUSSION

A. Mechanism

The mechanism of TCPP synthesis is show in Fig 2. 4-carboxy benzaldehyde and pyrrol react in presence of propionic acid. After Porphyrinogen formation from dipyrrole oxids, H₂TCPP will synthesized and recognaized with TLC.

B. UV-Visible spectrometer

The Solution of 10⁻⁵ M TCPP at pH 9 is pink and exhibits five absorption maxima; one in Soret band at 414 nm (3.5×10⁵ M⁻¹ cm⁻¹) and four maxima in the “Q” range 500-650 nm at 517, 554, 579 and 634 nm with the molar absorption coefficients of 1.2×10⁴, 6.5×10³, 5.2×10³ and 3.3×10³, respectively.

Spectra of porphyrin solutions during spectrophotometric titration are presented in Fig.4-a,b. On addition of Ag(I) ion, the absorption of free-base at 420 nm and 517 nm decreases whereas the absorption at 460 nm increased.

A plot of absorbance at 460 nm, the Soret of Ag(I)porphyrin, and at 517 nm, the major visible band of the free-base, as a function of the added silver ion concentrations is shown in Fig.5 a,b.
Fig. 5 (a) Plot of absorbance vs. [Ag+] at 460(nm) and (b) at 570 (nm) during spectrophotometric titration of H$_2$TCPP with Ag$^+$. 

C. Reaction mechanism

Assuming a reaction of the type:

$$n\text{Ag}^+ + H_2\text{TCPP} \leftrightarrow H_{2-n}\text{Ag}_n\text{TCPP} + n\text{H}^+$$

$$K = \frac{[H_{2-n}\text{Ag}_n\text{TCPP}][\text{Ag}^+]^n}{[H_2\text{P}][\text{Ag}^+]^n}$$

log $K$ = $n\log[H^+] + \log[\text{Ag}^+] - \log[H_2\text{P}] - n\log[\text{Ag}^+]$

where $n$ can be 1, 2, etc. one can derive the following:

$$\log((A_i - A)/(A - A_f)) = n\log[\text{Ag}^+] + \log K - n\log[H^+]$$

In "(5)" $A_i$, $A$, $A_f$ and $K$ represent absorbance at the beginning of the titration, absorbance during the titration corresponding to $[\text{Ag}^+]$, and absorbance at the end of the titration and the equilibrium constant respectively. Plots of log $((A_i - A)/(A - A_f))$ as a function of log $[\text{Ag}^+]$ gives straight line with a slope of "$n" and intercept of "$K".

$$V = \frac{d[A_gP]}{dt} = k_1[H_{2-n}\text{Ag}_n\text{TCPP}][\text{Ag}^+] - k_4[\text{Ag}_n\text{P}][H^+]$$

Fig. 6 Plot of $K_{obs} \times [\text{Ag}^+]$ vs $[\text{Ag}^+]^2$ for the reaction of Ag(I) with $H_2\text{TCPP}$

Absorption spectra of the porphyrin solutions and silver porphyrin are compared in Fig.7. The soret band of metalloporphyrins is shorter than porphyrins and four Q bands in porphyrins decrease to two bands in absorption spectra of metalloporphyrins.
The symmetry group of the free-base porphyrins is D$_{2h}$ due to the two hydrogen atoms on the diagonally located pyrrolic rings. In Ag$_2$TCPP the metal centre is located out of the ligand plane, distorting it and causing lower symmetry C$_2$. IR spectrum of metalloporphyrin is shown in Fig.8.

D. Theoretical investigation

Fig. 9 shows the proposed geometry of the sitting-atop complex which the Angels and bonds of Ag$_2$TCPP are determined by hyper program. One bond length of Ag-N is 1.87 Å and the other bond length is 2.3 Å. An activated complex of this type is also in conformity and this intermediate in solution termed AgTCPP.

HOMO and LUMO for H$_2$TCPP and Ag$_2$TCPP were calculated by Gaussian program and semi-empirical ZINDO/1 basis set. HOMO ($A_{1u}$, $A_{2u}$) is -8.377 eV and -5.63 eV for H$_2$TCPP and Ag$_2$TCPP respectively and LUMO (e$_g$) is -3.38 eV and -0.42 eV for H$_2$TCPP and Ag$_2$TCPP respectively.

IV. Conclusion

In this study, the Kinetics incorporation of silver in H$_2$TCPP was discussed and the metalloporphyrin was characterized by theoretical studies, UV-Vis and IR spectrum. Mechanism of reactions and theoretical study were investigated.
