Control of Chaotic Dynamical Systems using RBF Networks

Yoichi Ishikawa, Yuichi Masukake, and Yoshihisa Ishida

Abstract—This paper presents a novel control method based on radial basis function networks (RBFNs) for chaotic dynamical systems. The proposed method first identifies the nonlinear part of the chaotic system off-line and then constructs a model-following controller using only the estimated system parameters. Simulation results show the effectiveness of the proposed control scheme.

Keywords—Chaos, nonlinear plant, radial basis function network.

I. INTRODUCTION

CHAOS is a special feature of parametric nonlinear dynamical systems. It is usually difficult to accurately predict its future behavior. Recently, a family of artificial neural networks have gotten good results on the prediction and control of the nonlinear plants [1]-[6]. K. S. Narendra et al. [3] have proposed identification and control methods of nonlinear dynamical systems using multi-layered perceptron neural networks. On the other, K. B. Kim et al. [6] have presented control of chaotic dynamical systems using RBF network approximators and demonstrated its effectiveness. The RBF networks are well known for their stable learning capability and fast training.

In this paper, we propose a design method of model-following controller using RBF networks, which is robust to disturbance and change of system parameters, improving on their basic idea for the control of nonlinear systems. The proposed method is applied to the Duffing and the Lorenz systems and its effectiveness is presented.

II. PROBLEM STATEMENT

Consider a discrete chaotic dynamical system given by

\[ x(k+1) = Ax(k) + f_S[x(k)], \]

where \( f_S[x(k)] \) is the nonlinear part of the system dynamics. In (1), \( A \) is assumed to be known and \( f_S[x(k)] \) is unknown but the inputs and outputs can be measured. We rewrite (1) to the system with a scalar control input of the form

\[ x(k+1) = Ax(k) + f_S[x(k)] + bu(k), \]

where \( b = [1 \cdots 1]^T \).

Then, we can also define the system output by

\[ y_p(k) = \begin{bmatrix} 1 & \cdots & 0 \\ 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 1 \end{bmatrix} x(k) = x(k). \]

Let us assume that the difference equation of the reference model for the chaotic system is given by a second-order system

\[ y_m(k+1) = -a_1 y_m(k) - a_2 y_m(k-1) + b_m r(k) + b_m r(k-1), \]

where

\[ y_m(k) : \text{model output}, \]

\[ r(k) : \text{reference input}. \]

In [3], the error between the model and plant output is defined as

\[ e(k) = y_m(k) - y_p(k), \]

and the design method is based on the condition

\[ \lim_{k \to \infty} e(k) = 0. \]

Then, from the relations (2)-(6), we obtain

\[ bu(k) = -a_1 y_p(k) - a_2 y_p(k-1) + b_m r(k) + b_m r(k-1) - Ax(k) - f_S(k), \]

where \( f_S(k) = f_S[x(k)] \). In (8), due to the non-presence of an integrator, it is considered that the system is prone to the offsets caused by the step disturbance.

Now, let us assume that at the steady state the following condition is satisfied:

\[ e(k+1) = e(k). \]

In this case, if \( e(0) \neq 0 \), then \( \lim_{k \to \infty} e(k) \neq 0 \). Furthermore, it is not guaranteed about the stability at the steady state. These problems will be solved later. From (9)

\[ y_m(k+1) = y_m(k) - y_p(k), \]

By substituting (2) and (5) into (10) and replacing \( y_m(k) \) with \( y_p(k) \), we have

\[ bu(k) = bu(k-1) - a_1 y_p(k) - a_2 y_p(k-1) + b_m r(k) + b_m r(k-1) - Ax(k) - f_S(k). \]

In the above, due to the appearance of the term \( bu(k-1) \), the effect of an integrator operation is expected and it will become robust to change of system parameters. On the other, substituting (11) into (2), we obtain

\[ y_p(k) = y_m(k+1) + \]

\[ \text{effect of an integrator operation is expected and it will become robust to change of system parameters. On the other, substituting (11) into (2), we obtain} \]
\[ y_p(k+1) = -a_{mp}y_p(k) - a_{mn}y_n(k-1) + b_{mp}r(k) + b_{mn}r(k-1), \] (12)

It is clear that the following condition is satisfied for arbitrary initial value \( e(0) \).
\[ \lim_{k \to \infty} e(k) = 0. \] (13)

Furthermore, the stability of the proposed method is obvious from some simulation experiments.

III. NONLINEARITY COMPENSATION USING RBF NETWORKS

A. RBF Networks

Fig. 1 illustrates RBF networks (RBFNs) with \( N_i \) inputs, \( N_r \) radial basis functions (RBFs), and \( N_o \) outputs. In Fig. 1, each RBF is given by so-called a Gaussian response function:
\[ h_i = \exp \left( -\frac{||x - c_i||^2}{2\sigma^2} \right), \] (14)

where \( x = [x_1, x_2, \cdots, x_N]^T \) is the input vector, \( c_i \) is centroid vector of the \( i \)-th RBF, \( ||\cdot|| \) denotes \( L_2 \) norm, and \( \sigma \) is the radius. The output of each RBF, \( y_j (j = 1, 2, \cdots, N_o) \), is then given as the linearly weighted sum of \( h_i \), i.e.,
\[ y_j = \sum_i w_{ij} h_i \] (15)

where
\[ W = \begin{bmatrix} w_{11} & w_{12} & \cdots & w_{1N}\_o \\ w_{21} & w_{22} & \cdots & w_{2N}\_o \\ \vdots & \vdots & \cdots & \vdots \\ w_{N_i\_1} & w_{N_i\_2} & \cdots & w_{N_i\_N}\_o \end{bmatrix} \] (16)
is called as the weight matrix.

![RBF Networks](image)

B. Design of Approximator

In the design, the function \( f_S(k) \) in (1) is replaced with the output \( y(k) = [y_1(k), y_2(k), \cdots, y_N\_o(k)]^T \) of the RBFNs, namely
\[ f_S(k) = y(k). \] (17)

To estimate the weight matrix \( W \) of the RBFNs we apply the singular value decomposition (SVD) [7] instead of applying the conventional least squares. Namely, the following relation is considered:
\[ HW = Y \] (18)

with
\[ H = \begin{bmatrix} \tilde{h}_1(k-N+1) & \tilde{h}_2(k-N+1) & \cdots & \tilde{h}_{N_i\_1}(k-N+1) \\ \tilde{h}_1(k-N+2) & \tilde{h}_2(k-N+2) & \cdots & \tilde{h}_{N_i\_1}(k-N+2) \\ \vdots & \vdots & \cdots & \vdots \\ \tilde{h}_1(k) & \tilde{h}_2(k) & \cdots & \tilde{h}_{N_i\_1}(k) \end{bmatrix} \in \mathbb{R}^{N\_o \times N_i}, \]
\[ Y = \begin{bmatrix} y^T(k-N+1) \\ y^T(k-N+2) \\ \vdots \\ y^T(k) \end{bmatrix} \in \mathbb{R}^{N\_o}, \]

where \( N > N_o \) and \( \tilde{h}_i(k) = \sum_j h_j(k) \).

Applying the SVD, the matrix \( H \) can be rewritten:
\[ H = USV^T, \] (19)

where the matrix \( U = [u_1, u_2, \cdots, u_{N_i}] \in \mathbb{R}^{N_i \times N_i} \) and \( V = [v_1, v_2, \cdots, v_{N\_o}] \in \mathbb{R}^{N\_o \times N\_o} \) are orthogonal to each other such that \( U^TU = I_{N_i} \) and \( V^TV = I_{N\_o} \), respectively, and
\[ S = \text{diag}(\lambda_1, \lambda_2, \cdots, \lambda_{N\_o}) \] with \( \lambda_1 > \lambda_2 > \cdots > \lambda_{N\_o} \). Then, we assume that the last \((N\_o - r)\) diagonal entries satisfy the relation \( \lambda_{N\_o-r+1} = \lambda_{N\_o-r+2} = \cdots = \lambda_{N\_o} = 0 \), the diagonal matrix \( S \) is re-written as
\[ S = \begin{bmatrix} \sum_1 & 0 \\ 0 & 0 \end{bmatrix}, \] (20)

where \( S = \text{diag}(\lambda_1, \lambda_2, \cdots, \lambda_{r}) \) and \( r < N\_o \).

Finally, the matrix \( W \) can be estimated using the reduced-rank version \( S_r \) of the matrix \( S \):
\[ S_r = \begin{bmatrix} \sum_r & 0 \\ 0 & 0 \end{bmatrix}, \] (21)
\[ W = VS_rU^TY. \] (22)

IV. SIMULATION RESULTS

In the simulation study, the transfer function of the reference model is given in the form of a standard second-order system:
\[ G_m(s) = \frac{\omega_m^2}{s^2 + 2\zeta_m\omega_m s + \omega_m^2}, \] (23)

where \( \omega_m = 50 \text{[rad/sec]} \) and \( \zeta_m = 1 \). To obtain the difference equation of the reference model in discrete form, we used the zero-order hold method [8]. The sampling interval was 10 [msec]. Then, the coefficients of the reference model were \( a_{m1} = -1.213, a_{m2} = 0.368, b_{m0} = 0.090, \) and \( b_{m1} = 0.065 \), respectively. Throughout the simulation study, the reference input \( r(k) \) (with a total of 100 samples) was fixed as
\[ r(k) = \begin{cases} 1: & \text{if } k = 0,1,\ldots,24 \\ & \text{and } k = 50,51,\ldots,74, \\ 0: & \text{otherwise}. \end{cases} \]  

To study the immunity from the disturbance, the step disturbance at \( k = 40 \) with the magnitude \( d(40) = 0.05 \) is intentionally added to the plant input \( u(k) \). The structure of the proposed control system by SIMULINK is presented in Fig. 2.

**A. Example 1: Duffing System**

The continuous dynamics of the chaotic Duffing system is given by

\[
\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ 1.1 & -0.4 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ -x_1^3(t) + 1.8 \cos(1.8t) \end{bmatrix} 
\]  

(25)

Fig. 3 illustrates an example of the trajectory Duffing system.

Discretizing (25) with the sampling interval \( T_s = 10 \text{[msec]} \), we have

\[
x(k+1) = \begin{bmatrix} 1.0001 & 0.0100 \\ 0.0110 & 0.9961 \end{bmatrix} x(k) + \begin{bmatrix} 0 \\ 0.01(-x_1^3(k) + 1.8 \cos(1.8k)) \end{bmatrix} 
\]  

(26)

Off-line identification for the nonlinear part of the system is first performed. For the approximator of the Duffing system, the structure of the RBFNs is summarized in Table I.

**TABLE I**  
**STRUCTURE OF THE RBFNS FOR THE DUFFING SYSTEM**

<table>
<thead>
<tr>
<th>Number of hidden nodes</th>
<th>30</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of inputs, outputs</td>
<td>2, 2</td>
</tr>
<tr>
<td>Number of clustering samples</td>
<td>1000</td>
</tr>
<tr>
<td>Off-line training iteration</td>
<td>10000</td>
</tr>
</tbody>
</table>

The simulation result for \( x(k) \) of this tracking control is illustrated in Fig. 4, where the initial state was \( x(0) = [1 1]^T \). The dotted and solid lines show the model and plant outputs, respectively.

**B. Example 2: Lorenz System**

The continuous dynamics of the chaotic Lorenz system is given by

\[
\dot{x}(t) = \begin{bmatrix} -10 & -10 & 0 \\ 28 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ -x_1(t)x_2(t) \\ x_1(t)x_3(t) \end{bmatrix} 
\]  

(27)

Fig. 5 illustrates an example of the trajectory Lorenz system. Then, the discrete form of the Lorenz system is given by

\[
x(k+1) = \begin{bmatrix} 0.9179 & 0.0951 & 0 \\ 0.2663 & 1.0035 & 0 \\ 0 & 0 & 0.9736 \end{bmatrix} x(k) + \begin{bmatrix} 0 \\ 0 \\ -0.01x_1(k)x_3(k) + 0.01x_1(k)x_3(k) \end{bmatrix} 
\]  

(28)
For the Lorenz system, the RBFNs summarized in Table II was used as the approximator of the nonlinear part. The simulation result for $x_2(k)$ of this tracking control is presented in Fig. 6, where the initial state was $x(0) = [1 \ 1 \ -1]'$.

V. CONCLUSION

In this paper, a novel design method for the control of chaotic dynamical systems has been presented. It has been shown that the nonlinear part of the chaotic dynamical system can be estimated by the RBFNs. The simulation experiments have illustrates that the proposed method is effective for the model-following control of the chaotic systems.
