Modified Levenberg-Marquardt Method for Neural Networks Training

Amir Abolfazl Suratgar, Mohammad Bagher Tavakoli, and Abbas Hoseinabadi

Abstract—In this paper a modification on Levenberg-Marquardt algorithm for MLP neural network learning is proposed. The proposed algorithm has good convergence. This method reduces the amount of oscillation in learning procedure. An example is given to show usefulness of this method. Finally a simulation verifies the results of proposed method.

Keywords—Levenberg-Marquardt, modification, neural network, variable learning rate.

I. INTRODUCTION

The Error Back Propagation (EBP) algorithm [1]–[4] has been a significant improvement in neural network research, but it has a weak convergence rate. Many efforts have been made to speed up EBP algorithm [5]–[9]. All of these methods lead to little acceptable results. The Levenberg-Marquardt (LM) algorithm [4], [10]–[13] ensued from development of EBP algorithm dependent methods. It gives a good exchange between the speed of the Newton algorithm and the stability of the steepest descent method [11], that those are two basic theorems of LM algorithm. An attempt has been made to speed up LM algorithm with modified performance index and gradient computation [14], although it is unable to reduce error oscillation. Other effort with variable decay rate has been ensued to reduce error oscillation [15], but offered algorithm had low speed compared standard LM algorithm.

In this paper a modification is made on Learning parameter resulted in to decrease together both learning iteration and oscillation. A modification method by varying the learning parameter has been made to speed up LM algorithm. In addition, the error oscillation has been decreased.

Section II describes the LM algorithm. Section III the proposed form of the modification on learning parameter is introduced. In section IV a simulation is discussed.

II. THE LEVENBERG-MARQUARDT METHOD REVIEW

In the EBP algorithm, the performance index $F(w)$ to be minimized is defined as the sum of squared errors between the target outputs and the network’s simulated outputs, namely:

$$F(w) = e^T e$$

(1)

where $w = [w_1, w_2, ..., w_N]$ consists of all weights of the network, $e$ is the error vector comprising the error for all the training examples.

When training with the LM method, the increment of weights $\Delta w$ can be obtained as follows:

$$\Delta w = \left(J^T J + \mu I\right)^{-1} J^T e$$

(2)

where $J$ is Jacobian matrix, $\mu$ is learning rate which is to be updated using $\beta$ depending on the outcome. In particular, $\mu$ is multiplied by decay rate $\beta$ ($0 < \beta < 1$) whenever $F(w)$ decreases, whereas $\mu$ is divided by $\beta$ whenever $F(w)$ increases in a new step.

The standard LM training process can be illustrated in the following pseudo-codes,

1. Initialize the weights and parameter $\mu$ ($\mu=.01$ is appropriate).
2. Compute the sum of squared errors over all inputs $F(w)$.
3. Solve (2) to obtain the increment of weights $\Delta w$
4. Recomputed the sum of squared errors $F(w)$
5. Using $w + \Delta w$ as the trial $w$, and judge
   IF $F(w) < F(w)$ in step 2 THEN
   $$w = w + \Delta w$$
   $$\mu = \mu \cdot \beta$$
   Go back to step 2
   ELSE
   $$\mu = \frac{\mu}{\beta}$$
   go back to step 4
   END IF

III. MODIFICATION OF THE LM METHOD

Considering performance index is $F(w) = e^T e$ using the Newton method we have as:

Amir Abolfazl Suratgar is Assistant professor in the Electrical Engineering Department, University of Arak, Arak, Iran. (phone: +98-861-22 25 946; fax: +98-861-22 25 946; e-mail: a-surtagar@ araku.ac.ir).

Mohammad Bagher Tavakoli is Msc. Student of Electrical Engineering Department of Azad University, Arak, Iran (e-mail: m-tavakoli@ iau-arak.ac.ir).

Abbas Hoseinabadi is Msc. Student of Electrical Engineering Department of Azad University, Arak, Iran (e-mail: a-hoseinabadi@ iau-arak.ac.ir).
\( W_{k+1} = W_k - A_k^{-1} \cdot g_k \)  
(3) \( W_{k+1} = \)

\( A_k = \nabla^2 F(w) \bigg|_{w=w_k} \)  
(4) \( W_k - \left[ 2J^T (w_k) \cdot J(w_k) \right]^{-1} 2J^T (w_k) e(w_k) \)

\( g_k = \nabla F(w) \bigg|_{w=w_k} \)  
(5) \( \equiv W_k - \left[ J^T (w_k) \cdot J(w_k) \right]^{-1} J^T (w_k) e(w_k) \)

The gradient can write as:
\( \nabla F(x) = 2J^T e(w) \)
(7) \( G = H + \mu I \)

Where

\[ J(w) = \begin{bmatrix} \frac{\partial e_{i1}}{\partial w_1} & \frac{\partial e_{i1}}{\partial w_2} & \cdots & \frac{\partial e_{i1}}{\partial w_N} \\ \frac{\partial e_{i2}}{\partial w_1} & \frac{\partial e_{i2}}{\partial w_2} & \cdots & \frac{\partial e_{i2}}{\partial w_N} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial e_{iN}}{\partial w_1} & \frac{\partial e_{iN}}{\partial w_2} & \cdots & \frac{\partial e_{iN}}{\partial w_N} \end{bmatrix} \]

\( J(w) \) is called the Jacobian matrix.

Next we want to find the Hessian matrix. The \( k, j \) elements of the Hessian matrix yields as:

\[ \left[ \nabla^2 F(w) \right]_{k,j} = \frac{\partial^2 F(w)}{\partial w_k \partial w_j} \]
(9) \[ = 2\sum_{i=1}^{N} e_i(w) \frac{\partial^2 e_i(w)}{\partial w_k \partial w_j} \]

The Hessian matrix can then be expressed as follows:

\[ \nabla^2 F(W) = 2J^T (W) \cdot J(W) + S(W) \]
(10) \[ \text{Where} \]

\[ S(w) = \sum_{i=4}^{N} e_i(w) \cdot \nabla^2 e_i(w) \]
(11) \[ \text{If we assume that} \ S(w) \text{ is small, we can approximate the Hessian matrix as:} \]

\[ \nabla^2 F(w) \equiv 2J^T (w) J(w) \]
(12) \[ \text{Using (12) and (4) we obtain the Gauss-Newton method as:} \]

\[ The \text{advantage of Gauss-Newton is that it does not require calculation of second derivatives.} \]

(6) \[ \text{There is a problem the Gauss-Newton method is the matrix H}=J^T J \text{may not be invertible. This can be overcome by using the following modification.} \]

\[ \text{Hessian matrix can be written as:} \]

\[ G = H + \mu I \]
(14) \[ \text{Suppose that the eigenvalues and eigenvectors of H are} \ \{ \lambda_1, \lambda_2, \ldots, \lambda_n \} \text{ and} \ \{ z_1, z_2, \ldots, z_n \}. \text{Then:} \]

\[ Gz_i = \left[ H + \mu I \right] z_i = Hz_i + \mu z_i = \lambda_i z_i + \mu z_i = (\lambda_i + \mu) z_i \]
(15) \[ \text{Therefore the eigenvectors of G are the same as the eigenvectors of H,} \]

\[ \text{and the eigenvalues of G are} \ (\lambda_i + \mu). \text{The matrix G is positive definite by increasing} \mu \text{ until} \ (\lambda_i + \mu) > 0 \text{ for all i} \text{ therefore the matrix will be invertible.} \]

This leads to Levenberg-Marquardt algorithm:

\[ w_{k+1} = w_k - \left[ J^T (w_k) \cdot J(w_k) + \mu I \right]^{-1} J^T (w_k) e(w_k) \]
(16) \[ \Delta w_k = \left[ J^T (w_k) \cdot J(w_k) + \mu I \right]^{-1} J^T (w_k) e(w_k) \]
(17) \[ \text{As known, learning parameter,} \mu \text{ is illustrator of steps of actual output movement to desired output. In the standard LM method,} \mu \text{ is a constant number. This paper modifies LM method using} \mu \text{ as:} \]

\[ \mu = 0.01 e^T e \]
(18) \[ \text{Where} \ e \text{ is a} k \times 1 \text{ matrix therefore} \ e^T e \text{ is a} 1 \times 1 \text{ therefore} \ [J^T J + \mu I] \text{ is invertible. Therefore, if actual output is far than desired output or similarly, errors are large so, it converges to desired output with large steps.} \]

\[ \text{Likewise, when measurement of error is small then, actual output approaches to desired output with soft steps. Therefore error oscillation reduces greatly.} \]

IV. SIMULATION RESULTS

In this section we consider XOR gate as a case study. We simulate this gate with standard LM and modified LM. We use a Neural Network with two layers and the transfer function is as:
\[ f(\text{net}) = \frac{2}{1 + \exp(-\text{net})} - 1 \]  

(19)

Fig.1 shows the error of Neural Network simulation with standard LM and Fig.2 shows the result of modified LM. As described in Table I, the iteration of learning and the oscillation is reduced in modified LM.

Results of the standard LM and modified LM algorithms for XOR example are shown in Table I.
