Abstract—There are two common methodologies to verify signatures: the functional approach and the parametric approach. This paper presents a new approach for dynamic handwritten signature verification (HSV) using the Neural Network with verification by the Conjugate Gradient Neural Network (NN). It is yet another avenue in the approach to HSV that is found to produce excellent results when compared with other methods of dynamic. Experimental results show the system is insensitive to the order of base-classifiers and gets a high verification ratio.

Keywords—Signature Verification, MATLAB Software, Conjugate Gradient, Segmentation, Skilled Forgery, and Genuine.

I. INTRODUCTION

Signature verification is to evaluate whether a suspected signature is genuine or forgery. It’s widely used in the fields of finance and security. Usually three kinds of forgery can happen in signature verification. Random forgery is taking the genuine signature of others for that of the current user. Skilled forgery is produced with close imitations. It is hard to be discriminated from the genuine one only by shape variations. Simple forgery is produced with the knowledge of content but without close imitations. For example, the forger signs out of his/her memory on the genuine signature.

In this paper, multiple classifiers integration using the Neural Network with verification by the Conjugate Gradient Neural Network (NN) algorithm is proposed. This system is designed to detect both random and simple forgeries. In the rest part of Bajaj and Chaudhury[3] proposed a system consisting of sub-classifiers that are based on three sets of global features. Sansone and Vento [4] proposed a sequential three-stage multi-expert system, in which the first expert eliminates random and simple forgeries, the second isolates skilled forgeries, and the third gives the final decision by combining decisions of the previous stages together with reliability estimations. Baltzakis and Papamarkos [5] developed a two-stage neural network, in which the first stage gets the decisions from neural networks and Euclidean distance classifiers supplied by the global, grid and texture features, and the second combines the four decisions using a radial-base function (RBF) neural network.

This paper, section 2 discusses Quantifying Gradient Change in Images. Section 3 presents the SDM Analysis. Section 4 explains algorithm definitions. Section 5 mentions future work.

Finally, section 6 and 7 give our experimental results and conclude this paper.

II. QUANTIFYING GRADIENT CHANGE IN IMAGES

The majority of the generic shape recognition methods rely on using the topological features of an image. SDM quantifies the property of gradient change as the shape changes. The 16 level gray scale image obtained (in this study) is initially converted into a binary image by assigning every pixel value equal to or greater than 128 a value 1 and all others a value 0. The source image is skeletonized and divided into nine segments containing equal number of pixels. For each segment, its SDM feature is calculated. The set of rules employed can be summarized below.

Rule 1. The whole process proceeds in a horizontal manner, row by row. At any one time, two successive rows are under consideration.

Rule 2. The process continues unless all rows of the image pixels have been exhausted. Start with the first row.

Rule 3. Let’s call the black pixel found in row $i$ as $B_i$.

Rule 4. Find the distance between $B_i$ and $B_{i+1}$. Let’s say the distance is $S_i$.

Rule 5. Sum up all the distances for a total of $k$ rows, $SD = \sum_{i=1}^{k} S_i$; $SD$ is the String Distance for the whole segment. This is shown in Fig. 1 below with two examples illustrating positive and negative SDS.
**SD** represents the change in gradient as we traverse in downward direction which is summed up by considering any two adjacent rows at any one time. **SDs** are calculated for each of the nine segments. The overall procedure is described in the next section. From Fig. 1 (a) and (b), it is evident that **SDs** may have a zero value if the Fig. 1 (a) and (b) shapes coexist in the same segment. Hence multidirectional lines will contribute differently (positive and negative values) to the summed measurement. Also single horizontal and vertical lines will have zero **SD** values. This may be shown below in Fig. 2 (a) and (b).

![Image](attachment://image.png)

**Fig. 1 SD Calculations (a) (Negative Values); and (b) (Negative Values)**

For concave shapes, and Zero for shapes which are symmetrical around the x or y axis. However it is needed to include the extent of horizontal and vertical lines which are not properly measured by **SD** alone. Another parameter called String Line Measurement (**SLIM**) is therefore introduced. **SLIM** has a value 1 if a horizontal or vertical line is detected, otherwise it is 0. This **SLIM** value must be scaled to the **SD** measurement before it can be added to it. Also **SLIM** values must be modified to represent the contribution of longer lines as greater to the overall **SDM** value. This can be achieved by taking into consideration the total number of black pixels in the straight horizontal or vertical lines with respect to the total number of black pixels in the segment. The final equation used for the string distance measurement of segment i with a total of n V/H (vertical or horizontal) segments is in equation (1) below.

$$\text{SDM}_i = \alpha \text{ factor}_i + \sum_{j=1}^{n} \beta \text{ factor}_j$$

Where

- $\alpha \text{ factor}_i = \text{SD}_i$
- $\beta \text{ factor}_i = \text{SD}_i \times (\text{SLIM}_j \times \text{Black Pixels within V/H segment}_j)/(\text{Black Count}_i)$

Here **Black Count** represents the total number of black pixels within the individual segment (one of the nine) under consideration. Horizontal and Vertical scans were separately needed for each segment for identifying horizontal and vertical lines. If there is more than one black pixel in a row or a column, it indicates the presence of a horizontal or vertical line segment. Longer horizontal or vertical segments yield a higher value for the $\beta \text{ factor}$ and increase the overall value of **SDM**.

III. **SDM Analysis**

The overall analysis can be divided into three stages: image acquisition and preprocessing, feature extraction, and neural network analysis. For the draft as examining our system 77 persons were asked to sign using the pen for Casper Tablet PC Computer in Windows Journals Program, and for final different 5 persons also asked to sign as testing our proposed system as shown in Fig. 3 and used as database.

![Image](attachment://image.png)

**Fig. 3 Database**

The image was first skeletonized and segmented as shown in Fig. 4. The obtained skeleton by making use of a conditional erosion algorithm which eroded the original image with four successive passes: from left, right, up and down, using the condition: “erode if (next pixel is black) and (one or more surrounding pixels are black)”. 
The process continued until the image could no longer be eroded. The resultant image was clipped so that the edges of the image were confined within a fixed boundary as shown in Fig. 5.

The image was then segmented in 5 parts as in Fig. 5, each segment with its own binary address. The features ($SDM$ values) were extracted for each segment and the complete image was described by vector $S = (SDM_1, SDM_2, ..., SDM_n)$. In practice although for two different images, a few of the segments may yield identical $SDM$ values, it would be rare if all the five values were same for completely different shapes. The patterns obtained were used as inputs to the neural network for recognizing different signatures. The overall process can be shown in Fig. 6 with the following flowchart.

The skeletonized image can be shown in Fig. 7 below.

Image processing software was developed which segments the image and analyzes the partitioned segments individually. It can be seen from Fig. 7 (a) and (b) that $SDM$ values for different segments will vary across different images, e.g. for Fig. 7(a) segment (0, 0) it has a negative value, but it is nearly zero for the same segment in Fig. 7(b), then applied to the Conjugate Gradient N.N.

IV. ALGORITHM DEFINITION TRAINING & TESTING
A Multi-layer Neural Network trained using Conjugate Gradient classifies the authentication attempt of a user as who is the signer. The neural network is initially trained against a set of 77 valid signatures given by the user when he or she is first introduced to the system as well as a set of $m$ target signatures; the training process is shown in Fig. 8 with a goal of 0.001, the performance was 0.000999985, and 31 Epochs.
For testing, data was collected from 5 participants. Each participant was asked to sign his name ten times as consistently as possible. Most participants have not used a tablet PC before, which may have affected the consistency of their signatures. The result of testing the program is shown in Fig. 9.

**V. SOME EXAMPLES**

![Signature Example](image)

**VI. COMPARISON TESTS**

Compared with single feature set, our method reaches much better performance on random forgeries (refer to the last row in Table I). It may due to the fact that simple forgeries have smaller distances to the reference mean than random forgeries. Their introduction will decrease the relevant threshold, which in turn increases FRR will increase a bit accordingly. Based on the tests, we finally include 5 simple forgeries in the training dataset.

VII. CONCLUSION

Transforming the input before training yields much lower error, but is more sensitive. Most importantly, we have presented system can vary in security depending on the situation.

Uses for such a system range from securing a credit card transaction at the point of sale to user authentication on tablet PCs. We hope that this system will help future research in creating variable security HSV systems as well as systems which can select feature sets which are optimal for a specific user.

ACKNOWLEDGMENT

My deepest thanks are to Prof. Dr. Senol Bektas, and to Prof. Dr. Fakhraddin Mamedov. I would like to express my gratitude to my colleagues in the department. Also I would like to express my gratitude to my family.
