Volume Fraction Law for Stainless Steel on Inner Surface and Nickel on Outer Surface For FGM Cylindrical Shell

M.Hosseinjani Zamenjani1, A.R.Tahmasebi Birgani2, M.R.Isvandzibaei3

Abstract—Vibration of thin cylindrical shells made of a functionally gradient material composed of stainless steel and nickel is presented. The effects of the FGM configuration are studied by applying the forces of FG cylindrical shells. In this case, FG cylindrical shell has nickel on its outer surface and stainless steel on its inner surface. The study is carried out based on third order shear deformation shell theory. The objective is to study the natural frequencies, the influence of constituent volume fractions and the effects of configurations of the constituent materials on the frequencies. The properties are graded in the thickness direction according to the volume fraction power-law distribution. Results are presented on the frequency characteristics, the influence of the constituent various volume fractions on the frequencies.

Keywords—Nickel, Stainless Steel, Cylindrical shell.

I. INTRODUCTION

Stainless Steel are often used as load bearing structures for aircrafts, ships and buildings. Understanding of vibration behavior of cylindrical shells is an important aspect for the successful applications of cylindrical shells. Researches on free vibrations of cylindrical shells have been carried out extensively [1-5]. Recently, the present authors presented studies on the influence of boundary conditions on the frequencies of a multi–layered cylindrical shell [6]. In all the above works, different thin shell theories based on Love hypothesis were used. Vibration of cylindrical shells with ring support is considered by Loy and Lam [7]. The concept of functionally graded materials (FGMs) was first introduced in 1984 by a group of materials scientists in Japan [8-9] as a means of preparing thermal barrier materials. FGMs have attracted much interest as heat-shielding materials. FGMs are made by combining different materials using power metallurgy methods [10]. Vibration study of FG cylindrical shell structures is important. This cylindrical shell considered are composed of stainless steel and nickel where the volume fractions follow a power-law distribution.

II. FUNCTIONALLY GRADED MATERIALS

For the cylindrical shell made of FGM the material properties such as the modulus of elasticity $E$, Poisson ratio $\nu$ and the mass density $\rho$ are assumed as functions of the volume fraction $\phi$, and the mass density $\rho$ is assumed to be functions of $\phi$. According to the volume fraction power-law distribution. Results are presented on the frequency characteristics, the influence of the volume fractions follow a power-law distribution.

$E = (E_1 - E_2) \left( \frac{2Z + h}{2h} \right)^n + E_2$  \hspace{1cm} (1)

$\nu = (\nu_1 - \nu_2) \left( \frac{2Z + h}{2h} \right)^n + \nu_2$  \hspace{1cm} (2)

$\rho = (\rho_1 - \rho_2) \left( \frac{2Z + h}{2h} \right)^n + \rho_2$  \hspace{1cm} (3)

The third- order theory of Reddy used in the present study is based on the following displacement field:

\[ \begin{align*}
U_1 & = u_0(\alpha_1, \alpha_2) + \alpha_1 \phi(\alpha_1, \alpha_2) + \alpha_2 \beta(\alpha_1, \alpha_2) + \alpha_3 \sigma(\alpha_1, \alpha_2) + \alpha_4 \phi(\alpha_1, \alpha_2) \\
U_2 & = u_1(\alpha_1, \alpha_2) + \alpha_1 \phi(\alpha_1, \alpha_2) + \alpha_2 \beta(\alpha_1, \alpha_2) + \alpha_3 \sigma(\alpha_1, \alpha_2) + \alpha_4 \phi(\alpha_1, \alpha_2) \\
U_3 & = u_0(\alpha_1, \alpha_2)
\end{align*} \]  \hspace{1cm} (4)

These equations can be reduced by satisfying the stress-free conditions on the top and bottom faces of the laminates, which are equivalent to $\epsilon_{13} = \epsilon_{23} = 0$ at $Z = \pm \frac{h}{2}$. Thus

\[ \begin{align*}
U_1 & = u_0(\alpha_1, \alpha_2) + \alpha_1 \phi(\alpha_1, \alpha_2) - C_1 \alpha_2 \left( \frac{u_0}{R_1} + \phi \frac{\partial u_0}{\partial \alpha_1} \frac{\partial \alpha_2}{\partial \alpha_2} \right) \\
U_2 & = u_1(\alpha_1, \alpha_2) + \alpha_1 \phi(\alpha_1, \alpha_2) - C_1 \alpha_2 \left( \frac{u_1}{R_2} + \phi \frac{\partial u_1}{\partial \alpha_1} + \frac{\partial \alpha_1}{\partial \alpha_2} \right) \\
U_3 & = u_0(\alpha_1, \alpha_2)
\end{align*} \]
III. FORMULATION

Consider a cylindrical shell is shown in Fig.1. $R$ is the radius, $L$ is the length and $h$ is the thickness. The reference surface is chosen to be the middle surface of the cylindrical shell where an orthogonal coordinate system $x, \theta, z$ is fixed. The deformations of the shell with reference to this coordinate system are denoted by $U_x, U_{\theta}$ and $U_z$ in the $x, \theta$ and $z$ directions, respectively.

![Fig. 1 Geometry of a cylindrical shell](image)

For a thin cylindrical shell, plane stress condition can be assumed. The constitutive relation for a thin cylindrical shell is consequently given by the two-dimensional Hook's law as

$$\{\sigma\} = [Q]\{\varepsilon\}$$

(6)

where, $\{\sigma\}$ is the stress vector, $\{\varepsilon\}$ is the strain vector and $[Q]$ is the reduced stiffness matrix. The stress vector for plane stress condition is

$$\{\sigma\}^T = \begin{bmatrix} \sigma_{11} & \sigma_{12} & \sigma_{13} & \sigma_{23} \end{bmatrix}$$

(7)

where $\sigma_{11}$ is the stress in $x$ direction, $\sigma_{22}$ the stress in the $\theta$ direction and $\sigma_{12}$ is the shear stress on the $x\theta$ plane and $\sigma_{13}$ is the shear stress on the $xz$ plane and $\sigma_{23}$ is the shear stress on the $\theta z$ plane. The strain vector is defined as

$$\{\varepsilon\}^T = \begin{bmatrix} \varepsilon_{11} & \varepsilon_{12} & \varepsilon_{13} \end{bmatrix}$$

(8)

where $\varepsilon_{11}$ is the strain in $x$ direction, $\varepsilon_{22}$ the strain in the $\theta$ direction and $\varepsilon_{12}$ is the shear strain on the $x\theta$ plane and $\varepsilon_{13}$ is the shear strain on the $xz$ plane and $\varepsilon_{23}$ is the shear strain on the $\theta z$ plane. The reduced stiffness $[Q]$ matrix is given as

$$[Q] = \begin{bmatrix} Q_{11} & Q_{12} & 0 & 0 & 0 \\ Q_{12} & Q_{22} & 0 & 0 & 0 \\ 0 & 0 & Q_{44} & 0 & 0 \\ 0 & 0 & 0 & Q_{55} & 0 \\ 0 & 0 & 0 & 0 & Q_{66} \end{bmatrix}$$

(9)

For an isotropic cylindrical shell the reduced stiffness $Q_{ij}$ ($i, j=1, 2$ and $6$) are defined as

$$Q_{11} = Q_{22} = \frac{E}{1-\nu^2}$$

(10)

$$Q_{12} = \frac{\nu E}{1-\nu^2}$$

(11)

$$Q_{44} = Q_{55} = Q_{66} = \frac{E}{2(1+\nu)}$$

(12)

where $E$ is the Young's modulus and $\nu$ is Poisson's ratio. For a thin cylindrical shell the force and moment results are defined as

$$\begin{align*}
N_{11} &= k \sigma_{11} d\alpha \\
N_{22} &= k \sigma_{22} d\alpha \\
N_{12} &= k \sigma_{12} d\alpha \\
P_{11} &= k \sigma_{11} d\alpha \\
P_{22} &= k \sigma_{22} d\alpha \\
P_{12} &= k \sigma_{12} d\alpha \\
Q_{13} &= k \sigma_{13} d\alpha \\
Q_{23} &= k \sigma_{23} d\alpha \\
Q_{33} &= k \sigma_{33} d\alpha \\
R_{13} &= k \sigma_{13} d\alpha \\
R_{23} &= k \sigma_{23} d\alpha \\
R_{33} &= k \sigma_{33} d\alpha \\
\end{align*}$$

(13)

(14)

(15)

The constitutive equation is obtained as

$$\{N\} = [S]\{\varepsilon\}$$

(16)

where $\{N\}$ and $\{\varepsilon\}$ are, respectively, defined as

$$\begin{align*}
\{N\}^T &= \begin{bmatrix} N_{11} & N_{12} & M_{11} & M_{12} & M_{13} & Q_{13} & Q_{23} & Q_{33} & R_{13} & R_{23} & R_{33} \end{bmatrix} \\
\{\varepsilon\}^T &= \begin{bmatrix} \varepsilon_{11} & \varepsilon_{12} & \varepsilon_{13} & \varepsilon_{22} & \varepsilon_{23} & \varepsilon_{33} \end{bmatrix} \\
\end{align*}$$

(17)

(18)

and $[S]$ is defined as
where A, B, E, D, F, H and G are the extensional, coupling and bending stiffness matrices and \( Q_{ij} \) are functions of \( z \) for functionally gradient materials. Here \( A_{ij} \) denote the extensional stiffness, \( D_{ij} \) the bending stiffness, \( B_{ij} \) the bending-extensional coupling stiffness and \( E_{ij}, F_{ij}, G_{ij}, H_{ij} \) are the extensional, bending, coupling, and higher-order stiffness.

\[
\begin{bmatrix}
A & B & E \\
B & D & F \\
E & D & H \\
E' & G & H' \\
A' & D' & E' \\
D' & F' & G'
\end{bmatrix}
\]

(19)

The strain energy and kinetic energy of a cylindrical shell can be defined as

\[
U = \frac{1}{2} \iiint (\varepsilon)^T \sigma \, dV
\]

(21)

\[
T = \frac{1}{2} \iiint \left[ \frac{\partial \varepsilon_x}{\partial x} + \frac{\partial \varepsilon_y}{\partial y} + \frac{\partial \varepsilon_z}{\partial z} + \frac{\partial \phi_x}{\partial x} + \frac{\partial \phi_y}{\partial y} + \frac{\partial \phi_z}{\partial z} \right] \, dV
\]

(22)

where \( \rho \) is the mass density, \( \{\varepsilon\} \) is the strain vector and \( \{\sigma\} \) is the stress vector. By substituting from Eq. (6), the strain and kinetic energies can be written as

\[
U = \frac{1}{2} \int_{x_1}^{x_2} \int_{\theta_1}^{\theta_2} \int_{z_1}^{z_2} (S) \{\varepsilon\} \, Rd\theta \, dx
\]

(23)

\[
T = \frac{1}{2} \int_{x_1}^{x_2} \int_{\theta_1}^{\theta_2} \int_{z_1}^{z_2} \rho \left( \frac{\partial \varepsilon_x}{\partial x} + \frac{\partial \varepsilon_y}{\partial y} + \frac{\partial \varepsilon_z}{\partial z} + \frac{\partial \phi_x}{\partial x} + \frac{\partial \phi_y}{\partial y} + \frac{\partial \phi_z}{\partial z} \right) \, Rd\theta \, dx
\]

(24)

The displacement fields for a cylindrical shell can be written as:

\[
\begin{align*}
u_1 &= T \frac{\partial \phi(x)}{\partial x} \cos(n\theta) \cos(o t) \\
u_2 &= \bar{B} \phi(x) \sin(n\theta) \cos(o t) \\
u_3 &= \bar{C} \phi(x) \cos(n\theta) \cos(o t) \\
\phi_1 &= \bar{D} \frac{\partial \phi(x)}{\partial x} \cos(n\theta) \cos(o t) \\
\phi_2 &= \bar{E} \phi(x) \sin(n\theta) \cos(o t)
\end{align*}
\]

(25)
VI. RESULTS AND DISCUSSION

The functionally gradient material (FGM) considered is composed of stainless steel and nickel and its properties are graded in the thickness direction according to the volume fraction power-law distribution. The influence of constituent volume fractions is studied by varying the volume fractions of the stainless steel and nickel. This is carried out by varying the value of the power law exponent $N$. The effects of the FGM configuration are studied by studying the frequencies of FG cylindrical shells. Type FG cylindrical shell has Nickel on its inner surface and stainless steel on its outer surface. The material properties for stainless steel and nickel, calculated at $T = 300K$, are presented. In this section variations of natural frequencies for the circumferential wave number $n$ for functional graded cylindrical shells with different volume fractions are presented. Tables 1 and 2 show variations of natural frequencies for FG cylindrical shell. The influence of the constituent volume fraction on the frequencies for FG cylindrical shells has been found to be different. For the FG cylindrical shells, the natural frequencies decreased when $N$ increased. The natural frequencies for all values of $N$ lie between those for a stainless steel and Nickel cylindrical shells. For $N < 1$, the natural frequencies for FG cylindrical shells are higher.
