Controller Design for Euler-Bernoulli Smart Structures Using Robust Decentralized POF via Reduced Order Modeling

T.C. Manjunath¹, Student Member IEEE, and B. Bandyopadhyay², member IEEE

Abstract—This paper features the proposed modeling and design of a Robust Decentralized Periodic Output Feedback (RDPOF) control technique for the active vibration control of smart flexible multimodel Euler-Bernoulli cantilever beams for a multivariable (MIMO) case by retaining the first 6 vibratory modes. The beam structure is modeled in state space form using the concept of piezoelectric theory, the Euler-Bernoulli beam theory and the Finite Element Method (FEM) technique by dividing the beam into 4 finite elements and placing the piezoelectric sensor / actuator at two finite element locations (positions 2 and 4) as collocated pairs, i.e., as surface mounted sensor / actuator, thus giving rise to a multivariable model of the smart structure plant with two inputs and two outputs. Five such multivariable models are obtained by varying the dimensions (aspect ratios) of the aluminum beam, thus giving rise to a multimodel of the smart structure system. Using model order reduction technique, the reduced order model of the higher order system is obtained based on dominant eigen value retention and the method of Davison. RDPOF controllers are designed for the above 5 multivariable-multimodel plant. The closed loop responses with the RDPOF feedback gain and the magnitudes of the control input are observed and the performance of the proposed multimodel smart structure system with the controller is evaluated for vibration control.

Keywords—Smart structure, Euler-Bernoulli beam theory, Periodic output feedback control, Finite Element Method, State space model, SISO, Embedded sensors and actuators, Vibration control, Reduced order model

I. INTRODUCTION

PIEZOELECTRIC materials are capable of altering the structure’s response through sensing, actuation and control. Piezoelectric elements can be incorporated into a laminated composite structure, either by embedding it or by mounting it onto the surface of the host structure [7]. Vibration control of any system is always a formidable challenge for any control system designer. Active control of vibrations relieves a designer from strengthening the structure from dynamic forces and the structure itself from extra weight and cost. The need for intelligent structures such as smart structures arises from the high performance requirements of such structural members in numerous applications. Intelligent structures are those which incorporate actuators and sensors that are highly integrated into the structure and have structural functionality, as well as highly integrated control logic, signal conditioning and power amplification electronics [3].

A vibration control system consists of 4 parts, viz., actuator, controller, sensor and the system or the plant, which is to be controlled. When an external force \( f_{ext} \) is applied to the beam, it is subjected to vibrations. These vibrations should be suppressed. Fully active actuators like the Piezoelectrics, MR Fluids, Piezoceramics, ER Fluids, Shape Memory Alloys, PVDF, etc., can be used to generate a secondary vibrational response in a mechanical system. This could reduce the overall response of the system plant by the destructive interference with the original response of the system, caused by the primary source of vibration [2], [3], [10], [13].

Extensive research in modeling of piezoelectric materials in building actuators and sensors for structure is reported. Investigations of Crawley and Luus [3] emphasized on the derivation of sensor / actuator modeling of piezo-electric materials. Moreover, the control analysis of cantilever beams using these sensors / actuators have been studied by Bailey and Hubbard [2]. Culshaw [7] gave a brief introduction to the concept of smart structure, its benefits and applications. Hanagud, et al., [13] developed a Finite Element Model (FEM) for an active beam with many distributed piezoceramic sensors / actuators coupled by signal conditioning systems and applied optimal output feedback control.

Fanson and Caughey [10] performed some experiments on a beam with piezoelectrics using positive position feedback. Hwang and Park [12] presented a FE model for piezoelectric sensors and actuators. Balas [16] presented the feedback control of flexible structures. Choi et al. [8] discussed about the control techniques of flexible structures using distributed piezoelectric sensors / actuators. Feedback control of vibrations in mechanical systems has numerous applications, like in aircrafts, active noise and shape control, acoustic control, control of antennas, earthquake, structural health monitoring, control of space structures and in the control of...
flexible manipulators. Fault tolerant control of smart structures using POF when one of the actuator fails to function was proposed in [19]. Manjunath and Bandopadhyay proposed a AVC scheme for the best location (and for the best model) of the sensor / actuator pair on a beam modeled with Euler-Bernoulli beam theory in [17] and [18].

The outline of the paper is as follows. A brief review of related literature was given in Section 1. Section 2 gives a brief introduction to the modeling technique (sensor / actuator model, finite element model, state space model) of the smart flexible cantilever beam for a multivariable case with two inputs and two outputs. A brief review of the controlling technique, viz., the periodic output feedback control technique, multimodel synthesis, design of the LMI formulation, RDPOF design, model order reduction technique and the design of the robust decentralized periodic output feedback controller to control the first 6 modes of vibration of the system via reduced order modeling is discussed in section 4. The simulation results are shown in section 5 followed by the concluding section.

II. MATHEMATICAL MODELING OF SMART BEAM

Fig. 2 A smart flexible beam divided into 4 FE with piezo patches placed at even FE positions 2 and 4

Consider a flexible cantilever beam made of aluminum bonded with piezoelectric sensor / actuator all along the length of the beam as shown in Fig. 1. The dimensions and properties of the flexible beam and piezoelectric sensor / actuator are given in Tables I and II respectively. The flexible cantilever beam as shown in Fig. 1 is divided into a number of finite elements viz., 4 as shown in Fig. 2. The piezoelectric sensor / actuator is bonded to the master structure at finite element positions numbering 2 and 4, thus giving rise to a Multiple Input Multiple Output (MIMO) system with 2 actuator inputs \( u_1, u_2 \) to the actuators and 2 sensor outputs, \( y_1, y_2 \) from the sensors.

A. Modeling of Regular and Piezo Elements of Beam

To start with, we consider the modeling of the regular beam element and the piezoelectric beam element as shown in the Fig. 1. The dynamic model for the smart structure is developed using the Finite Element Method (FEM) [12], [24]. The smart cantilever beam model is developed using a piezoelectric beam element, which includes the sensor and actuator dynamics and a regular beam element based on Euler-Bernoulli theory assumptions. The piezoelectric beam element is used to model the regions where the piezoelectric element is bonded as sensor / actuator and the rest of the structure is modeled by the regular beam elements.

In modeling and analysis of the smart beam, the following assumptions are made. The perfect bonding or the adhesive between the beam and the sensor / actuator and the thin film electrode surfaces have been assumed to add no mass or stiffness to the sensor / actuator, i.e., neglected. The cable capacitance between sensor and signal-conditioning device has been considered negligible and the temperature effects
have been neglected. The signal conditioning device gain $(G_i)$ is assumed as 100. The free vibration characteristics of a flexible beam is governed by the following fourth order differential equation [20], [25]

$$
E I \frac{\partial^4 w(x,t)}{\partial t^4} + \rho A \frac{\partial^2 w(x,t)}{\partial t^2} = 0,
$$

where $w$ is the transverse displacement of the beam and is a function $x$ and $t$, $x$ being the distance of the local coordinate from the fixed end, $t$ being the time and $c$ is a constant which is given by $\sqrt{\frac{E I}{\rho A}}$.

$E, I, \rho$ and $A$ are the young’s modulus, moment of inertia, mass density and area of the beam respectively. When a system vibrates, it undergoes to and fro motion and so all positions vary with time and therefore, the system has velocities and accelerations. Mass times acceleration as inertia force appears in the governing differential equation of the beam which is given in Eq. (1), i.e., the equation of motion involves a fourth order derivative w.r.t. $x$ and a second order derivative w.r.t. time.

The piezoelectric element is obtained by sandwiching the regular beam element between two thin piezoelectric layers as shown in Fig. 2. The bottom layer is acting as a sensor and the top layer acts as an actuator. The beam element is assumed to have two structural DOF ($w, \theta$) at each nodal point and an electrical DOF: a transverse deflection and an angle of rotation or slope. Since the voltage is constant over the electrode, the number of electrical DOF is one for each element.

The electrical DOF is used as a sensor voltage or actuator voltage when the piezoelectric material attached to the structure behaves as sensor or actuator. Corresponding to the 2 DOF, a transverse shear force and a bending moment acts at each nodal point. At each nodal point, counteracting moments induced by the piezoelectric actuators will be acting. The bending moment resulting from the applied voltage to the actuator adds a positive finite element being the moment at node 1 while subtracting it at node 2.

The deflection behavior of the beam element is best described by a displacement function $W(x)$, which is the solution of Eq. (1). It is desirable that this function satisfies the differential equation of equilibrium for the beam element. The solution of the Eq. (1) is assumed as a cubic polynomial function of $x$ given by [20], [25]

$$
W(x) = a_1 + a_2 x + a_3 x^2 + a_4 x^3,
$$

where the constants $a_1$ to $a_4$ are obtained using the boundary conditions of the beam at the nodal points (fixed end and free end) as

$$
\begin{bmatrix}
  a_1 \\
  a_2 \\
  a_3 \\
  a_4
\end{bmatrix} = \begin{bmatrix}
  l_b^4 & 0 & 0 & 0 \\
  4 l_b^3 & 0 & 0 & 0 \\
  6 l_b^2 & -2 l_b^2 & 3 l_b & -l_b^2 \\
  2 & l_b & -2 l_b & l_b^2
\end{bmatrix} \begin{bmatrix}
  w_1 \\
  \theta_1 \\
  w_2 \\
  \theta_2
\end{bmatrix},
$$

where $w_i, \theta_1$ and $w_2, \theta_2$ are the DOF’s at the node 1 (fixed end) and node 2 (free end) respectively.

The Eq. (2) is rearranged in the final form as

$$
[W(x)] = [n^T] [q],
$$

where $[n^T]$ gives the shape functions of the beam $f_i(x)$, $i = 1...4$ as

$$
[n^T] = \begin{bmatrix}
  f_1(x) & f_2(x) & f_3(x) & f_4(x)
\end{bmatrix},
$$

where

$$
\begin{bmatrix}
  1 - 3 x^2 + 2 x^3 \\
  -2 x^2 + x^3 \\
  3 x^2 - 2 x^3 \\
  -x^2 + x^3
\end{bmatrix},
$$

and

$$
\begin{bmatrix}
  w_1 \\
  \theta_1 \\
  w_2 \\
  \theta_2
\end{bmatrix} = \begin{bmatrix}
  \frac{\partial W}{\partial x} \\
  \frac{\partial^2 W}{\partial x^2} \\
  \frac{\partial W}{\partial t} \\
  \frac{\partial^2 W}{\partial t^2}
\end{bmatrix} \begin{bmatrix}
  f_1(x) & f_2(x) & f_3(x) & f_4(x)
\end{bmatrix} = [n^T] [q],
$$

for the beam shown in Fig. 1. The displacement, its first, second spatial derivatives and its time derivative in matrix form is given by $W(x), W'(x), W''(x)$ and $W(t)$ and is given by

$$
W' = [n^T] [q],
$$

$$
\begin{bmatrix}
  \frac{\partial W}{\partial x} \\
  \frac{\partial^2 W}{\partial x^2} \\
  \frac{\partial W}{\partial t} \\
  \frac{\partial^2 W}{\partial t^2}
\end{bmatrix} = \begin{bmatrix}
  f_1(x) & f_2(x) & f_3(x) & f_4(x)
\end{bmatrix} \begin{bmatrix}
  w_1 \\
  \theta_1 \\
  w_2 \\
  \theta_2
\end{bmatrix},
$$

$$
W'' = [n^T] [q],
$$

$$
\begin{bmatrix}
  \frac{\partial W}{\partial x} \\
  \frac{\partial^2 W}{\partial x^2} \\
  \frac{\partial W}{\partial t} \\
  \frac{\partial^2 W}{\partial t^2}
\end{bmatrix} = \begin{bmatrix}
  f_1(x) & f_2(x) & f_3(x) & f_4(x)
\end{bmatrix} \begin{bmatrix}
  w_1 \\
  \theta_1 \\
  w_2 \\
  \theta_2
\end{bmatrix}.
$$
B. Piezoelectric Strain Rate Sensors And Actuators

The linear piezoelectric coupling [22] between the elastic field and the electric field is expressed by the direct and the converse piezoelectric equations as

\[ D = d T + \varepsilon^T E, \quad S = s^E T + d E, \]  

(11)

where \( T \) is the stress, \( S \) is the strain, \( E \) is the electric field, \( D \) is the dielectric displacement, \( \varepsilon \) is the permittivity of the medium, \( s^E \) is the compliance of the medium and \( d \) is the piezoelectric constant.

C. Sensor Equation

The direct piezoelectric equation is used to calculate the output charge created by the strain in the structure [20], [25]. Since no external field is applied to the sensor layer, the electric displacement is given as

\[ D = d_31^* E_p \varepsilon_x = e_{31} \varepsilon_x, \]  

(12)

where \( e_{31} \) is the piezoelectric stress / charge constant, \( E_p \) is the Young’s modulus and \( \varepsilon_x \) is the strain of the testing structure at a point on the beam.

The total charge \( Q(t) \) developed on the sensor surface is the spatial summation of all the point charges developed on the sensor layer. Since the current \( i(t) = \frac{dQ(t)}{dt} \) suggests that the closed-circuit current signal generated in a piezoelectric lamina is proportional to the strain rate of the testing structure, we obtain

\[ i(t) = z e_{31} b \int_0^{l_p} \mathbf{n}_T^T \mathbf{q} \, dx, \]  

(13)

where \( z = \frac{l_a}{2} + l_p \), \( b \) is the width of the beam, \( l_p \) being the length of the piezo-sensor and \( \mathbf{n}_T \) is the second spatial derivative of shape function of the flexible beam. This current is converted into the open circuit sensor voltage \( V^s \) using a signal-conditioning device with the gain \( G_e \) and applied to the actuator with the controller gain \( K_c \). The sensor output voltage is obtained as

\[ V^s(t) = G_e e_{31} z b \int_0^{l_p} \mathbf{n}_T^T \mathbf{q} \, dx, \]  

(14)

which is nothing but the signal conditioning gain \( G_e \) multiplied by the closed-circuit current \( i(t) \) generated by the piezoelectric lamina. Substituting for \( \mathbf{n}_T^T \) from Eq. (9) and \( \mathbf{q} \) from Eq. (10) and simplifying, we get the sensor voltage for a two node finite element of the beam as

\[ V^s(t) = \begin{bmatrix} 0 & -G_e e_{31} z b & 0 & G_e e_{31} z b \end{bmatrix} \begin{bmatrix} \dot{\theta}_1^T \\ \dot{\theta}_2^{131} \\ \dot{\theta}_1^{13} \\ \dot{\theta}_2^{13} \end{bmatrix} \begin{bmatrix} w_1^{131} \\ w_2^{131} \\ w_1^{13} \\ w_2^{13} \end{bmatrix}, \]  

(15)

which can be further expressed as a scalar-vector product

\[ V^s(t) = \mathbf{p}^T \mathbf{q}. \]  

(16)

where \( \mathbf{p} \) is the time derivative of the modal coordinate vector \( \mathbf{q} \), \( \mathbf{p}^T \) is a constant vector which depends on the type of sensor, its characteristics and its location on the beam. Note that the sensor output is a function of the second spatial derivative of the mode shape. This sensor voltage is given as input to the controller and the output of the controller (which is nothing but the control input to the actuator, i.e., the actuator voltage) is the controller gain \( K_c \) multiplied by the sensor voltage \( V^s(t) \). Thus, the input voltage to the actuator \( V^a(t) \) is given by

\[ V^a(t) = K_c V^s(t). \]  

(17)

Substituting for \( V^s(t) \) from Eq. (14) in Eq. (17), we get

\[ V^a(t) = K_c G_e e_{31} z b \int_0^{l_p} \mathbf{n}_T^T \mathbf{q} \, dx. \]  

(18)

D. Actuator Equation

The actuator strain is derived from the converse piezoelectric equation. The strain developed \( \varepsilon_a \) on the actuator layer is given by [20], [25]

\[ \varepsilon_a = d_31 E_f, \]  

(19)

where \( d_31 \) and \( E_f \) are the piezo strain constant and the electric field respectively. When the input to the piezoelectric actuator \( V^a(t) \) is applied in the thickness direction \( t_a \), the electric field, \( E_f \) which is the voltage applied \( V^a(t) \) divided by the thickness of the actuator \( t_a \); and the stress, \( \sigma_a \) which is the actuator strain multiplied by the young’s modulus \( E_p \), of the piezoe actuator layer are given by

\[ E_f = \frac{V^a(t)}{t_a}, \]  

(20)

and

\[ \sigma_a = E_p d_31 \frac{V^a(t)}{t_a}. \]  

(21)
The resultant moment \( M_A \) acting on the beam is determined by integrating the stress throughout the structure thickness as

\[
M_A = E_p \int_0^l \sigma z V^a(t) \, dz,
\]

where \( \sigma = \frac{(t_p + t_b)}{2} \), is the distance between the neutral axis of the beam and the piezoelectric layer. Finally, the control force applied by the actuator is obtained as

\[
f_{ctrl} = E_p \int_0^l \sigma z \left[ \mathbf{n}_z \, dx \right] V^a(t),
\]

or can be expressed as a scalar vector product as

\[
f_{ctrl} = \mathbf{h} V^a(t) = \mathbf{h} u(t),
\]

where \( \mathbf{n} \) is the first spatial derivative of the shape function of the flexible beam, \( \mathbf{h} \) is a constant vector which depends on the type of actuator and its location on the beam, given by

\[
\mathbf{h} = \left[- E_p \int_0^l \sigma z \, dz \right] \left[ \begin{array}{c} 0 \\ E_p \int_0^l \sigma z \, dz \end{array} \right] \text{ and } u(t) \text{ is nothing but the control input to the actuator, i.e., } V^a(t) \text{ from the controller. If any external forces described by the vector } f_{ext} \text{ are acting on the beam, then the total force vector becomes}
\]

\[
f^\prime = f_{ext} + f_{ctrl}.
\]

E. Dynamic Equation of Smart Structure

The strain energy \( U \) and the kinetic energy \( T \) for the beam element with uniform cross section in bending is [20], [25],

\[
U = \frac{E_b I_b}{2} \int_0^l \left[ \frac{\partial^2 w}{\partial x^2} \right]^2 dx = \frac{E_b I_b}{2} \int_0^l \left[ \frac{w''(x,t)}{w''(x,t)} \right] \left[ \frac{w''(x,t)}{w''(x,t)} \right] dx,
\]

\[
T = \frac{\rho A_b}{2} \int_0^l \left[ \dot{w}(x,t)^2 \right] dx = \frac{\rho A_b}{2} \int_0^l \left[ \dot{w}(x,t) \right] \left[ \dot{w}(x,t) \right] dx.
\]

The equation of motion of the regular beam element is obtained by the Lagrangian equation for the regular beam element as

\[
\frac{d}{dt} \left[ \frac{\partial T}{\partial q_i} \right] - \frac{\partial U}{\partial q_i} = \left[ F_i \right],
\]

which after simplification yields as

\[
M^b \ddot{q} + K^b q = f^b(t),
\]

where

\[
[M^b] = \rho A_b \int_0^l \left[ \mathbf{n}_z \right]^T \left[ \mathbf{n}_z \right] dx,
\]

\[
[M_{ij}^b] = \rho A_b \int_0^l f_i(x) f_j(x) \, dx
\]

and

\[
[K^b] = E_b I_b \int \left[ \mathbf{n}_z \right]^T \left[ \mathbf{n}_z \right] dx,
\]

\[
[K_{ij}^b] = E_b I_b \int f_i^\prime(x) f_j^\prime(x) \, dx.
\]

Finally, after simplification, we get

\[
M^b = \frac{\rho A_b I_b}{420} \begin{bmatrix} 156 & 22 l_b & 54 & -13 l_b \\ 22 l_b & 4 l_b & 13 l_b & -3 l_b^2 \\ 54 & 13 l_b & 156 & -22 l_b \\ -13 l_b & -3 l_b^2 & -22 l_b & 4 l_b \\ \end{bmatrix}
\]

and

\[
K^b = \frac{E_b I_b}{l_b} \begin{bmatrix} 12/l_b^2 & 6/l_b & -12/l_b^2 & 6/l_b \\ 6/l_b & 4 & -6/l_b & 2 \\ -12/l_b^2 & -6/l_b & 12/l_b^2 & -6/l_b \\ 6/l_b & 2 & -6/l_b & 4 \end{bmatrix}
\]

where \( M^b, K^b \) are the local mass matrix, the local stiffness matrix of the regular beam element.

Similarly, the lagrangian equation of motion for the piezoelectric beam element is obtained as

\[
M^p \ddot{q} + K^p q = f^p(t),
\]

where \( M^p \) and \( K^p \) are the piezoelectric beam element mass matrix and stiffness matrix and are given as

\[
M^p = \frac{\rho A_p I_p}{420} \begin{bmatrix} 156 & 22 l_p & 54 & -13 l_p \\ 22 l_p & 4 l_p^2 & 13 l_p & -3 l_p^2 \\ 54 & 13 l_p & 156 & -22 l_p \\ -13 l_p & -3 l_p^2 & -22 l_p & 4 l_p^2 \end{bmatrix},
\]

\[
K^p = \frac{E I}{l_p} + 2 E_p l_p, \quad l_p = \frac{1}{12} b t_b^3 + b t_a \left( \frac{l_b + t_a}{2} \right)^2
\]

and

\[
\rho A = g \left( \rho p t_b + 2 \rho p t_a \right).
\]

The dynamic equation of the smart structure is obtained by using both the regular and piezoelectric beam elements given by Eqs. (29) and (36). The mass and stiffness of the bonding or the adhesive between the master structure and the sensor / actuator pair is neglected. The mass and stiffness of the entire beam, which is divided into 4 finite elements is assembled using the FEM technique [12], [24] and the assembled matrices (global matrices), \( \mathbf{M} \) and \( \mathbf{K} \) are obtained. The equation of motion of the smart structure is finally given by

\[
\mathbf{M} \ddot{\mathbf{q}} + \mathbf{K} \mathbf{q} = \mathbf{f}_{ext} + \mathbf{f}_{ctrl} = \mathbf{f}^\prime,
\]

where \( \mathbf{M}, \mathbf{K}, \mathbf{q}, \mathbf{f}_{ext}, \mathbf{f}_{ctrl}, \mathbf{f}^\prime \) are the global mass matrix, global stiffness matrix of the smart beam, the vector of displacements and slopes, the external force applied to the beam, the controlling force from the actuator and the total force coefficient vector respectively. The mass matrix \( \mathbf{M} \),
stiffness matrix $K$ and the control force vector $h^T$ in the system equation can be varied by changing the position and number of regular and piezoelectric beam elements.

The generalized coordinates are introduced into the Eq. (42) using a transformation $q = T g$ in order to reduce it further such that the resultant equation represents the dynamics of the first 6 vibratory modes $\omega_i$ to $\omega_6$ of the smart flexible cantilever beam. $T$ is the modal matrix containing the eigen vectors representing the first 6 vibratory modes. This method is used to derive the uncoupled equations governing the motion of the free vibrations of the system in terms of principal coordinates by introducing a linear transformation between the generalized coordinates $q$ and the principal coordinates $g$. The Eq. (42) now becomes

$$M \ddot{g} + K g = f_{ext} + f_{ctrl1} + f_{ctrl2},$$

where $f_{ctrl1}$ and $f_{ctrl2}$ are the control force coefficient vectors to the actuators from the controller.

Multiplying Eq. (43) by $T^T$ on both sides and further simplifying, we get

$$M^* \ddot{g} + K^* g = f_{ext} + f_{ctrl1} + f_{ctrl2},$$

where $M^* = T^T M T$, $K^* = T^T K T$, $f_{ext} = T^T f_{ext}$,

$$f_{ctrl1}^{*} = T^T f_{ctrl1} \quad i = 1 \text{ to } 2.$$

$M^*$, $K^*$, $f_{ext}$, $f_{ctrl1}$, $f_{ctrl2}$ represents the generalized mass matrix, the generalized stiffness matrix, the generalized external force vector and the generalized control force vectors respectively.

The generalized structural modal damping matrix $C^*$ (Raleigh proportional damping) is introduced into the Eq. (44) by using

$$C^* = \alpha M^* + \beta K^*, \quad \text{where } \alpha \text{ and } \beta \text{ are the damping constant respectively.}$$

The dynamic equation of the smart flexible cantilever beam developed as is

$$M^* \ddot{g} + C^* \dot{g} + K^* g = f_{ext} + f_{ctrl},$$

where $f_{ctrl} = f_{ctrl1} + f_{ctrl2}$.

**F. State Space Model of the Smart Structure**

The state space model of the smart flexible cantilever beam is obtained as follows [20], [25]. Let

$$g = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_6 \\ x_7 \\ x_8 \\ \vdots \\ x_{12} \end{bmatrix} \quad \text{and} \quad \dot{g} = \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \vdots \\ \dot{x}_6 \\ \dot{x}_7 \\ \dot{x}_8 \\ \vdots \\ \dot{x}_{12} \end{bmatrix}.$$

Thus,

$$\dot{x}_1 = x_7, \quad \dot{x}_2 = x_8, \quad \dot{x}_3 = x_9,$$

$$\dot{x}_4 = x_{10}, \quad \dot{x}_5 = x_{11}, \quad \dot{x}_6 = x_{12}.$$

and Eq. (46) now becomes

$$M^* \ddot{g} + C^* \dot{g} = f_{ext} + f_{ctrl}.$$

which can be further simplified as

$$\begin{bmatrix} \dot{x}_7 \\ \dot{x}_8 \\ \dot{x}_9 \\ \dot{x}_{10} \\ \dot{x}_{11} \\ \dot{x}_{12} \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \end{bmatrix} - M^{-1} C^* f_{ext} + M^{-1} f_{ctrl}.$$

The generalized external force coefficient vector is

$$f_{ext} = T^T f_{ext} = T^T f(r(t)),$$

where $r(t)$ is the external force input (impulse disturbance) to the beam.

The generalized control force coefficient vector is

$$f_{ctrl}^{*} = T^T f_{ctrl1} = T^T h V_i^a(t) = T^T h u_i(t), \quad i = 1 \text{ to } 2,$$

where the voltages $V_i^a(t)$ are the input voltages to the actuators 1 and 2 from the controllers respectively, and are nothing but the control inputs $u_i(t)$ to the actuators, $h_i$ is a constant vector which depends on the actuator type, its position on the beam and is given by

$$h = \begin{bmatrix} E_p d_{i1} b \Sigma_{1} \end{bmatrix} = \begin{bmatrix} \alpha_k \end{bmatrix},$$

for one piezoelectric actuator element (say, for the piezo patch placed at the finite element position numbering 2), where $E_p d_{i1} b \Sigma_{1}$ is the actuator constant. So, using the Eqs. (52) and (53) in Eq. (51), the state space equation for the smart beam is represented as
The sensor output is given by

\[ y(t) = \mathbf{p}^T \mathbf{q} = \mathbf{p}^T \mathbf{T} g = \mathbf{p}^T \mathbf{T} \]

which can be written as

\[
\begin{bmatrix}
  y_1 \\
  y_2 \\
  \vdots \\
  y_N
\end{bmatrix} =
\begin{bmatrix}
  \mathbf{p}_1^T \\
  \mathbf{p}_2^T \\
  \vdots \\
  \mathbf{p}_N^T
\end{bmatrix} \begin{bmatrix}
  x_1 \\
  x_2 \\
  \vdots \\
  x_N
\end{bmatrix}
\]

for a multivariable case with 2 inputs and 2 outputs. i.e.,

\[ y(t) = \mathbf{C}^T x(t) + \mathbf{D} u(t), \]

The multivariable state space model (state equation and the output equation) of the smart structure developed for the system thus [20], [25], is given by

\[ \mathbf{x} = \mathbf{A} x(t) + \mathbf{B} u(t) + \mathbf{E} r(t), \]

\[ y(t) = \mathbf{C}^T x(t) + \mathbf{D} u(t), \]
The state space models of the remaining 4 models are obtained similarly. The characteristics of the smart flexible cantilever beam of the model 1 are given in Table III.

Similarly, the characteristics of the other 4 models are obtained.

### III. Design of POF Controller via the Reduced Order Modeling

In the following section, we develop the control strategy for the multivariable cum multimodel representation of the developed smart structure model using the periodic output feedback control law [4]-[6], [15], [26], [27] with 1 actuator input $u$ and 1 sensor output $y$ for the 5 models of the smart structure plant as shown in Fig. 2. The problem of pole assignment by piecewise constant output feedback was studied by Chammas and Leondes [4]-[6] for LTI systems with infrequent observations. They have shown that by the use of a periodically time-varying piecewise constant output feedback gain, the poles of the discrete time control system could be assigned arbitrarily (within the natural restriction that they should be located symmetrically with respect to the real axis) using the POF technique. Since the feedback gains are piecewise constants, their method could easily be implemented, guarantees the closed loop stability and indicated a new possibility. Such a control law can stabilize a much larger class of systems.

#### A. Review of Periodic output feedback control technique

Consider a LTI CT system [4]-[6], [27] given by

$$ x(k+1) = A x(k) + B u(k), \quad y(k) = C x(k), $$

which is sampled with a sampling interval $\tau$ secs and given by the discrete linear time invariant system (called as the tau system) as

$$ x(k \tau) = \Phi x(k \tau) + \Gamma u(k), \quad y(k) = C x(k), $$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$, $y \in \mathbb{R}^p$ and $\Phi, \Gamma, C$ are constant matrices of appropriate dimensions. The following control law is applied to this system. The output $y$ is measured at the time instant $t = k \tau$, $k = 0,1,2,\ldots$. We consider constant hold function because they are more suitable for implementation. An output-sampling interval is divided into $N$ sub-intervals of length $\Delta = \tau / N$ and the hold function is assumed to be constant on these sub-intervals as shown in the Fig. 3. Thus, the control law becomes

$$ u(t) = K_i (k \tau), \quad \Delta = \tau / N $$

for $i = 0,1,2,\ldots,(N-1)$. Note that a sequence of $N$ gain matrices $\{K_0, K_1, \ldots, K_{N-1}\}$, when substituted in Eq. (67), generates a time-varying piecewise constant output feedback gain $K(t)$ for $0 \leq t \leq \tau$.

![Graphical illustration of the POF control law](image-url)
Consider the following system, which is obtained by sampling the system in Eq. (65) at sampling interval of $\Delta = \tau / N$ and denoted by $\langle \Phi, \Gamma, C \rangle$ called as the delta system:

$$x(k+1) = \Phi x(k) + \Gamma u(k), \ y(k) = C x(k), \quad (68)$$

A useful property of the control law in Eq. (67) is given by the following lemma which states as “Given an observable pair $(A, B) \in \mathfrak{M}^{n \times n} \times \mathfrak{M}^{n \times m}$ and $\text{rank}(B) = m$, the controllability index of the system w.r.t any particular column of $b_i$ of $B$ is the minimum value of $V_i$ such that the column $A^i B$ is dependent on the columns before it in the following series $\{b_i, b_{i+1}, \ldots, b_m, Ab_i, Ab_{i+1}, \ldots, A^i b_i, \ldots, A^i b_m\}$. (69)

The controllability index of the entire system being defined as $\nu = \max(V_i)"$.

Assume $\langle \Phi, C \rangle$ is observable and $\langle \Phi, \Gamma \rangle$ is controllable with controllability index $\nu$ such that $N \geq \nu$, then it is possible to choose a gain sequence $K_i$, such that the closed-loop system, sampled over $\tau$, takes the desired self-conjugate set of eigen values $[4]-[6], [15], [27]$. Define

$$K = \begin{bmatrix} K_0 \\ K_1 \\ \vdots \\ K_{N-1} \end{bmatrix}, \quad \quad \quad (70)$$

$$u(k\tau) = \begin{bmatrix} u(k\tau) \\ u(k\tau+\Delta) \\ \vdots \\ u(k\tau+\tau-\Delta) \end{bmatrix} \quad (71)$$

then, a state space representation for the system sampled over $\tau$ is

$$x(k\tau + \tau) = \Phi^N x(k\tau) + \Gamma u(k\tau), \ y(k) = C x(k), \quad (72)$$

where $\Gamma = [\Phi^{N-1} \Gamma, \ldots, \Gamma]$. Applying POF in Eq. (67), i.e., $K y(k\tau)$ is substituted for $u(k\tau)$, the closed loop system becomes

$$x(k\tau + \tau) = (\Phi^N + \Gamma KC) x(k\tau). \quad (73)$$

The problem has now taken the form of static output feedback [23], [28]. Eq. (73) suggests that an output injection matrix $G$ be found such that

$$\rho(\Phi^N + GC) < 1, \quad (74)$$

where $\rho(\cdot)$ denotes the spectral radius. By observability, one can choose an output injection gain $G$ to achieve any desired self-conjugate set of eigen values for the closed-loop matrix $(\Phi^N + GC)$ and from $N \geq \nu$, it follows that one can find a POF gain which realizes the output injection gain $G$ by solving

$$\Gamma K = G \quad (75)$$

for $K$. The controller obtained from this equation will give the desired behaviour, but might require excessive control action. To reduce this effect, we relax the condition that $K$ exactly satisfy the linear equation and include a constraint on it. Thus, we arrive at the following in the inequality equations:

$$\|K\| < \rho_1, \ |\Gamma K - G| < \rho_2. \quad (76)$$

Using the schur complement, it is straightforward to bring these conditions in the form of linear matrix inequalities [11], [28] as

$$\begin{bmatrix} -\rho_1^2 I & K \\ K^T & -I \end{bmatrix} < 0, \begin{bmatrix} -\rho_2^2 I & (\Gamma K - G) \\ (\Gamma K - G)^T & -I \end{bmatrix} < 0. \quad (77)$$

In this form, the LMI toolbox of MATLAB can be used for the synthesis of $K$.

B. Multimodel Synthesis

For the multimodel representation of a plant, it is necessary to design a controller that will robustly stabilize the multimodel system. Multimodel representation of plants can arise in several ways. When a non-linear system has to be stabilized at different operating points, linear models are sought to be obtained at those operating points. Even for parametric uncertain linear systems, different linear models can be obtained for extreme points of the parameters. These models are then used for the stabilization of the systems [4]-[6].

Consider a family of plants, $S = \{A_i, B_i, C_i\}$ defined by

$$\dot{x} = A_i x + B_i u, \ y = C_i x, \quad i = 1, 2, \ldots, M. \quad (78)$$

By sampling the above system in (78) at the rate of $1 / \Delta$, we get a family of discrete systems $\mathcal{S} = \{\Phi_i, \Gamma, C_i\}$. Assume that $\langle \Phi^N_i, C_i \rangle$ are observable. Then, we can find the output injection gains $G_i$ such that $\langle \Phi^N_i + G_i C_i \rangle$ has the required set of poles. Now, consider the augmented system defined as follows:

$$\Phi = \begin{bmatrix} \Phi_1 & 0 & \cdots & 0 \\ 0 & \Phi_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \Phi_M \end{bmatrix}, \quad \Gamma = \begin{bmatrix} \Gamma_1 \\ \Gamma_2 \\ \vdots \\ \Gamma_M \end{bmatrix}, \quad G = \begin{bmatrix} G_1 \\ G_2 \\ \vdots \\ G_M \end{bmatrix}. \quad (79)$$

The linear equation

$$\Phi N^{-1} \Gamma = \cdots = \Gamma \quad (80)$$

has a solution if $\langle \Phi, \Gamma \rangle$ is controllable with controllability index $\nu$ and $N \geq \nu$. This POF gain realizes the designed
\( G_i \) for all the plants of the family. It has been shown in [27], that the controllability of the individual plant models generically implies the controllability of the augmented system. The controller obtained from the above equation will produce the desired behaviour, but might require excessive control action. To reduce this gain effect, we relax the condition that Eq. (80) has to be satisfied exactly and include a constraint on the gain. Thus, we consider the following inequalities:

\[
\begin{bmatrix} K \\ \Gamma \end{bmatrix} \leq \rho_1 I, \quad \|\Gamma K - G_i\| \leq \rho_2, \quad i = 1, \ldots, M, \tag{81}
\]

where \( \rho_1 \) and \( \rho_2 \) represent the upper bounds on the spectral norms of \( K \) and \( \gamma \Gamma K - G \) and \( M = 5 \) respectively.

These 2 objectives have been expressed by the upper bounds on matrix norms and each should be as small as possible. \( \rho_1 \) small means low noise sensitivity and \( \rho_2 \) small means that the POF controller with gain \( K \) is a good approximation of the original design. It should be noted here that closed loop stability requires \( \rho_2 < 1 \), i.e., the eigenvalues which determine the error dynamics must lie within the unit disc. This can be formulated in the framework of LMI as follows:

\[
\begin{bmatrix} -\rho_{ii}^2 I & K \\ K^T & -I \end{bmatrix} \leq 0, \quad \begin{bmatrix} -\rho_{ii}^2 I & (\Gamma K - G) \\ (\Gamma K - G)^T & -I \end{bmatrix} < 0, \tag{82}
\]

Here, the LMI toolbox of MATLAB can be used for the design of \( K \) [11], [28]. The RDPOF controller obtained by this method requires only constant gains and is hence easier to implement.

C. Robust Decentralized Periodic Output Feedback

In POF, for multimodel synthesis, the gain matrix is generally full. This results in the control input of each plant being a function of the output of all the plants. Decentralized robust POF control can be achieved by making the off-diagonal elements of \( \{K_i, K_1, \ldots, K_{n-1}\} \) matrices zero.

So, the structure of \( K_i (i = 0, 2, \ldots, N - 1) \) matrix is assumed as \( K_i = \text{diag}[k_{i1}, k_{i2}, k_{i3}, \ldots]; i = 0, 1, \ldots, N - 1. \)

With this structure of \( K_i \), the problem can be formulated in the framework of LMI using Eqs. (81) and (82) and the desired matrices obtained. Now, it is evident that the control input of each model of the plant is a function of the output of that plant only and this makes the smart structure controller design using POF a robust decentralized one.

D. Model order reduction technique

For many complex processes or when the modes of a dynamical system are very high, the order of the state matrix may be quite large. It would be difficult to work with these large scale dynamical systems [21] in their original form. In such cases, it is common to study the process by approximating it to a simpler model. These mathematical models correspond to approximating a system by its dominant pole-zeros in the complex plane. They generally require empirical determination of the system parameters.

Many different methods have been developed to accomplish the purpose by estimating the ‘dominant’ part of the large system and finding a simpler (or reduced order) system representation that has its behaviour akin to the original system. Here, we discuss the model order reduction technique based on the dominant modes retention. It is usually possible to describe the dynamics of a physical dynamical system by a number of linear differential equations with constant coefficients as

\[
\dot{x} = Ax + Bu, \quad y = Cx, \tag{83}
\]

where \( A \) is a \((n \times n)\) matrix.

The simulation and design of controllers become very cumbersome if the order of the system goes high. One way to overcome this difficulty is to develop a reduced model of the higher order system. One of the well-known techniques is based on dominant eigenvalue retention based on the Davison technique [9], [14]. By this method, a system of higher order can be numerically approximated to one of smaller order. The method suggests that a large \((r \times r)\) system can be reduced to a simpler \((r \times r)\) model \((r \leq n)\) by considering the effects of the \( r \) most dominant (dominant in the sense of being closest to the instability) eigenvalues alone.

The principle of the method is to neglect the eigenvalues of the original system that are farthest from the origin and retain only the dominant eigenvalues and hence dominant time constants of the original system in the reduced order model. This implies that the overall behaviour of the approximate system will be very similar to that of the original system since the contribution of the unretained eigenvalues to the system response are important only at the beginning of the response, whereas the eigenvalues retained are important throughout the whole of the response. For the system represented by the Eq. (83), consider the linear transformation,

\[
x = Pz, \tag{84}
\]

which transforms the model Eq. (83) into the following form,

\[
\dot{z} = \hat{A}z + \hat{B}u, \quad y = \hat{C}z, \tag{85}
\]

where \( \hat{A} \) is a \((r \times r)\) matrix and

\[
\hat{A} = P^{-1}AP, \quad \hat{B} = P^{-1}B \quad \text{and} \quad \hat{C} = CP. \tag{86}
\]

Here, \( \hat{A} \) is in the diagonal form as

\[
\hat{A} = \text{diag} [\lambda_1, \lambda_2, \ldots, \lambda_r] \tag{87}
\]

and \( \text{Re}(\lambda_i) \geq \text{Re}(\lambda_j) \geq \ldots \geq \text{Re}(\lambda_r). \tag{88} \)

Further, assume that only \( r \) eigenvalues are dominant, i.e., the order of the reduced model is \( r \) and partition the model in Eq. (85) as

\[
\dot{z}_1 = \hat{A}_1 z_1 + \hat{B}_1 u, \quad \dot{z}_2 = \hat{A}_2 z_2 + \hat{B}_2 u, \quad y = \hat{C}_1 z_1 + \hat{C}_2 z_2 \tag{89}
\]

where

\[
\hat{A}_1 = \text{diag} [\lambda_1, \lambda_2, \ldots, \lambda_r], \quad \hat{A}_2 = \text{diag} [\lambda_{r+1}, \lambda_{r+2}, \ldots, \lambda_n], \quad \hat{B}_1 = \text{first } r \text{ rows of } \hat{B}, \quad \hat{B}_2 = \text{remaining } (n-r) \text{ rows of } \hat{B} \tag{90}
\]
and are respectively \((r \times r), (n-r) \times (n-r), (r \times m)\) and \((n-r) \times m\) matrices obtained by portioning of \(A\) and \(B\) suitably. In Eq. (89), the order of \(z_i\) is \(r\) and that of \(z_2\) is \((n-r)\). Now, because the contribution of the modes represented by the eigenvalues \(\lambda_{r+1}, \lambda_{r+2}, \ldots, \lambda_n\) is not significant, it may be assumed that \(z_2 = 0\), whereby we have from Eq. (84),
\[
\begin{bmatrix}
x_1 \\
x_2
\end{bmatrix} = \begin{bmatrix} P_{11} & P_{12} \\
P_{21} & P_{22}
\end{bmatrix} z_1,
\]
where \(P_{11}\) and \(P_{21}\) are respectively, \((r \times r)\) and \((n-r) \times r\) submatrices obtained by portioning of \(P_i\) and \(z_1, z_2\) are respectively, \(r\) and \((n-r)\) dimensional state vectors corresponding to the original state variables. It follows from Eq. (91) that
\[
z_i = P_{1i}^{-1} x_i,
\]
with which the model in Eq. (89) can be transformed to
\[
\dot{x}_i = P_{1i} \dot{A} P_{1i}^{-1} x_i + P_{1i} \dot{B} u = A_i x_i + B_i u\tag{93}
\]
\[
y = C_i P_{1i}^{-1} x_i + C_i x_i = C_i x_i
\]
Moreover, from Eqns. (91), and (92), we have
\[
x_2 = P_{2i} P_{1i}^{-1} x_i.
\tag{94}
\]
Thus, the original \(n\)th order model represented by Eq. (83) is reduced to an \(r\)th order model given by Eq. (93). The state variables of the approximate model are the same as the first \(r\) state variables of the original higher-order model. The remaining state variables are given in terms of the first \(r\) state variables by Eq. (94).

E. RDPOF Control Design via reduced order model for multistem model

Let us consider a family of plants \(S = \{A_i, B_i, C_i\}\) defined by
\[
\dot{x} = A_i x + B_i u, \quad y = C_i x, \quad i = 1, 2, \ldots, M.
\tag{95}
\]
The discrete time invariant systems with sampling interval \(\tau\) seconds can be represented as
\[
x(k+1) = \Phi_i x(k) + \Gamma_i u(k), \quad y(k) = C_i x(k).
\tag{96}
\]
The adjoint or the dual for the above systems would be
\[
\dot{x}(k+1) = \Phi_i^T x(k) + \Gamma_i^T \dot{u}(k), \quad \dot{y}(k) = \Gamma_i \dot{z}(k).
\tag{97}
\]
There exists a transformation \(V_i\), such that,
\[
\dot{\hat{x}} = V_i \dot{\hat{z}}
\tag{98}
\]
transforms the above system in Eq. (97) into the following block diagonal modal form as
\[
\dot{\hat{\xi}}(k+1) = \Phi_i \hat{\xi}(k) + \Gamma_i \hat{\dot{u}}(k), \quad \hat{y}(k) = \Gamma_i \hat{\dot{z}}(k),
\tag{99}
\]
where
\[
\Phi_i = \begin{bmatrix} \Phi_{1i} & 0 \\ 0 & \Phi_{2i} \end{bmatrix}, \quad \Gamma_i = \begin{bmatrix} C_{1i} \\ C_{2i} \end{bmatrix}, \quad \Gamma_i = \begin{bmatrix} \Gamma_{1i} & \Gamma_{2i} \end{bmatrix}.
\tag{100}
\]
and the eigen values are arranged in the order of their dominance. We now extract an \(r\)th order model, retaining the \(r\) dominant eigen values, by truncating the above systems. Using Eqns. (99) and (100), we get
\[
\dot{\hat{\xi}}(k+1) = \Phi_i \hat{\xi}(k) + \Gamma_i \hat{\dot{u}}(k), \quad \hat{y}(k) = \Gamma_i \hat{\dot{z}}(k).
\tag{101}
\]
Let \(\hat{u}(k) = \Sigma_i \hat{\xi}_i\) be a stabilizing control for the reduced order model in Eq. (101). Thus, the closed loop reduced model \(\{\Phi_i + \Sigma_i \Gamma_i, \Sigma_i\}\) becomes stable. Now,
\[
\dot{\hat{\xi}} = [I_i : 0_{r \times (n-r)}] \hat{\xi} + [I_i : 0_{r \times (n-r)}] V_i^{-1} \hat{\dot{z}}.
\tag{102}
\]
Moreover, from Eqns. (100), we get
\[
\hat{u}(k) = S_i [I_i : 0_{r \times (n-r)}] V_i^{-1} \hat{\dot{z}} = S_i \hat{\dot{z}}
\tag{103}
\]
which makes the closed loop system \(\{\Phi_i + \Sigma_i \Gamma_i, \Sigma_i\}\) stable. But the eigen values of \(\{\Phi_i + \Sigma_i \Gamma_i, \Sigma_i\}\) and \(\{\Phi_i + \Sigma_i \Gamma_i, \Sigma_i\}\) are the same. So, \(\{\Phi_i + \Sigma_i \Gamma_i, \Sigma_i\}\) will also be stable. Thus, \(S_i = G_i\) is the output injection gain for the system in Eq. (96). Using these output injection gains \(G_i\), the following inequalities are solved.
\[
\|K\| < \rho_1, \quad \|\Gamma_i K - G_i\| < \rho_2, \quad i = 1, \ldots, M.
\tag{104}
\]
The controller obtained from the above equation will give desired behaviour, but might require excessive control action. To reduce this effect, we relax the condition that \(K\) exactly satisfy the above linear equation and include a constraint on the gain \(K\). Thus, this can be formulated in the framework of Linear Matrix Inequalities (LMI) as given in the following equation
\[
\begin{bmatrix} -\rho_i^2 I & K \\ K^T & -I \end{bmatrix} < 0, \quad \begin{bmatrix} -\rho_i^2 I & \Gamma_i (K - G_i) \\ (\Gamma_i K - G_i)^T & -I \end{bmatrix} < 0.
\tag{105}
\]
Here, the LMI toolbox of MATLAB can be used for the design of \(K\) [11], [28]. If the LMI constraints given in Eqns. (104) and (105) are solved by using the above \(G_i\), the robust periodic output feedback gain matrix may become full. This results in the control input of each model being a function of the outputs of all the models. To obtain the RDPOF control, the off-diagonal elements of \(K_{ij}, K_{i1}, \ldots, K_{M_1}\) matrices are made equal to zero as a result of which the control input to each actuator is a function of the output of that corresponding sensor only. This makes the POF control technique a robust decentralized one and is more feasible.

IV. CONTROL SIMULATIONS OF THE SMART BEAM

The finite element and the state space model of the smart cantilever beam is developed in MATLAB using Euler-Bernoulli beam theory. The flexible cantilever beam is divided into 4 finite elements and the sensor and actuator as colocated pairs at finite element positions 2 and 4 respectively, thus giving rise to a multivariable beam with 2 inputs and 2 outputs. By varying the thickness of the beam from 0.5, 0.6,
0.7, 0.8 and 1 mm, 5 multivariable models are obtained. These 5 MIMO models give rise to a multimodel smart structure plant. A 12th order state space model of the system is obtained on retaining the first 6 modes of vibration of the system. Simulations are carried out in MATLAB.

The POF control techniques discussed in the previous sections is used to design a controller to suppress the 1st 6 vibration modes of a cantilever beam through the smart structure concept for the various multivariable models of the smart beam. RDPOF feedback based reduced model order controller is designed for multimodel smart structure system using the developed multivariable state space model and its performance is evaluated for the Active Vibration Control.

The first task in designing the POF controller is the selection of the sampling interval $\tau$. The maximum bandwidth for all the sensor / actuator locations on the beam are calculated (here, the 6th vibratory mode of the plant) and then by using existing empirical rules for selecting the sampling interval based on bandwidth, approximately 10 times of the maximum 6th vibration mode frequency of the system has been selected. The sampling interval used is $\tau = 0.004$ seconds. The number of sub-intervals $N$ is chosen to be 10.

An external force $f_{ext}$ of 1 Newton is applied for duration of 50 ms at the free end of the beam for all the 5 models of the Fig. 2. RDPOF Controllers via the reduced order modeling has been designed to control the first 6 modes of vibration of the smart cantilever beam for the 5 models of the smart structure. A large 12th order system of $(12 \times 12)$ is reduced to a simpler 6th order model of $(6 \times 6)$, by considering the effects of the 6 most dominant (dominant in the sense of being closed to instability) eigen values. The eigen values of the original system that are farthest from the origin are neglected and only dominant eigen values of the original system in the reduced order model is retained. The open loop and closed loop responses of the system are observed.

The periodic output feedback gain matrix $K$ for the system given is obtained by solving $\Gamma K = G$ using the LMI optimization method [11], [28] which reduces the amplitude of the control signal $u$. For convenience, only the closed loop impulse responses (sensor outputs $y_1$ and $y_2$) with RDPOF feedback gain $K$ of the system and the variation of the control signal $u_1$ and $u_2$ with time for the multivariable-multimodel system are shown in Figs. 4 - 13 respectively.

The 5 multivariable models of the smart structure system are considered for designing the RDPOF feedback controller via the reduced order model using the LMI technique approach of MATLAB. The discrete models are obtained for sampling time of $\tau = 0.004$ seconds. The reduced order models are computed from the adjoint discrete models discussed in the previous sections. Using the method discussed in the previous sections, stabilizing gain matrices $S_{i,j}$ is obtained for the reduced order model using the DLQR theory.

Using aggregation techniques [1], the output injection gain $G_i$ can be calculated for the higher order (actual) models. This POF gain can be obtained which approximately realizes the designed $G_i$ for all the models of the family. Here, as we are dealing with robust stabilization, we have to find a $K$ which will satisfy $\Gamma_j K = G_j$, $(i = 1 to 5)$ all these equations using the LMI approach. The gain sequences of $K$ are chosen $10 \ (K_1, K_2, \ldots, K_{10})$. In our problem considered $N = 10$ had given good results. Using the output injection gains $G_i$, LMI constraints given in Eqns. (104) and (105) are solved for different values of $\rho_1$ and $\rho_2$ to find the robust decentralized gain matrix $K$ for the actual models via the reduced order model.

The closed loop responses with this RDPOF feedback gain $K$ via the reduced order model for all the models are satisfactory and are able to stabilize the outputs. The eigen values of $\{\Phi^s + GC\}$ are found to be within the unit circle. It is found that the designed robust decentralized FOS feedback controllers via the reduced order model provided good damping enhancement for the various multivariable models of the smart structure plant.

The proposed robust decentralized control for the multimodel smart structure system can be applied simultaneously to all the models and results in satisfactory response behaviour to damp out the vibrations, which can be seen from the simulation results in section 5. The input applied to each actuator of the model is a function of the output of that respective sensor only, which makes the control technique a robust, decentralized one. The RDPOF gain is

VI. CONCLUSIONS

Robust Decentralized Periodic Output Feedback Controller is designed and proposed for the multivariable smart structure using the various models of the single plant via the reduced order modeling. Simulations are done in Matlab and the various responses are obtained for the designed state space based FE model of the smart flexible cantilever beam. Through the simulation results, it is shown that when the plant is placed with the designed robust decentralized POF controller, the models performs well and the stability is guaranteed.

In the control law, the control input to each actuator of the multivariable plant’s multimodel is a function of the output of that corresponding sensor only and the gain matrix has got all off-diagonal elements zero. This makes the POF control technique a robust decentralized one. This would render better control and is more feasible. The robust decentralized POF controller designed by the above method requires only constant gains and hence is easier to implement. Closed loop responses are simulated for the various multivariable models of the smart structure plant.

A new algorithm is proposed for the design of robust decentralized controllers for a multivariable system using POF feedback technique via the reduced order model. The computation of the output injection gain, which is needed to obtain the decentralized POF feedback based smart structure system, becomes very tedious when a number of modes, especially greater than 5 are considered. Here, a output injection gain is computed from the reduced order model of the smart system and using the aggregation techniques, an output injection gain can be obtained for the higher order (actual model). The simulation results shows the effectiveness of the proposed method.

The RDPOF feedback gain which realizes this output injection gain, can be obtained for the actual model. It is found that the designed and proposed robust controller via the reduced order model provides good damping enhancement for the models of the smart structure system. Thus, an integrated finite element model to analyze the vibration suppression capability of a smart cantilever beams with surface mounted piezoelectric devices based on Euler-Bernoulli beam theory and reduced order modeling is proposed in this paper.

NOMENCLATURE (LIST OF SYMBOLS)

\( f_{ext} \) External force input
\( l_b \) Length of the beam
\( b \) Width of the beam
\[ E_b \] Young's modulus of beam
\[ \rho, \rho_p \] Mass density of beam
\[ \alpha, \beta \] Structural constants
\[ t_b \] Thickness of beam
\[ t_a \] Thickness of actuator
\[ t_s \] Thickness of sensor
\[ \rho_p \] Mass density of piezoelectric
\[ \theta, X, Y, Z \] The 3 axis of 3D space
\[ \dot{w} \] Linear velocity
\[ W \] External work done
\[ t \] Time in secs
\[ d_{31} \] Piezoelectric strain constant
\[ g_{31} \] Piezoelectric stress constant
\[ \theta \] Bending angle (rotation about \( Y \) axis)
\[ E_p \] Young’s modulus of piezoelectric
\[ w \] Time dependent transverse displacement of \( Z \) axis
\[ l_p \] Length of the piezoelectric patch
\[ I \] Mass moment of inertia of the beam element
\[ A \] Area of cross section of beam element
\[ T, U \] Kinetic energy and strain energy
\[ a_i \] (i=1, 2, 3, 4) Unknown coefficients
\[ b_j \] (j=1, 2, 3) Unknown coefficients
\[ q \] Vector of displacements and slopes
\[ \dot{q} \] Strain rate
\[ K_b \] Stiffness matrix of regular beam element (local stiffness matrix)
\[ M_b \] Mass matrix of the regular beam element (local mass matrix)
\[ K_p \] Stiffness matrix (local) of piezoelectric beam element
\[ M_p \] Mass matrix (local) of piezoelectric element
\[ A_p \] Area of the piezoelectric patch
\[ E_f \] Electric field
\[ M, K \] Mass & stiffness of regular beam element, assembled matrices (global)
\[ D \] Dielectric displacement
\[ e \] Permittivity of the medium
\[ S^E \] Compliance of the medium
\[ d \] Piezoelectric constant
\[ Q(t) \] Charge developed on the sensor surface
\[ i(t) \] Current generated by the sensor surface (due to the strain)
\[ e_{31} \] Piezoelectric stress / charge constant
\[ V^s \] Sensor voltage \( V^s \)
\[ G_c \] Signal-conditioning device with gain
\[ K_c \] Controller gain \( K_c \)
\[ p^r \] Constant vector, which depends
\[ h^r \] Constant vector, depends on sensor / actuator characteristics
\[ V^a(t) \] Actuator voltage
\[ V^s(t) \] Sensor voltage
\[ M_A \] Resultant moment acting on the beam
\[ f_{con} \] Control force applied by the actuator because of electric field
\[ \dot{f} \] Total force coefficient vector
\[ T \] Modal matrix containing eigenvectors representing the 1st 6 modes
\[ M^* \] Generalized mass matrix
\[ K^* \] Generalized stiffness matrix
\[ f_{ext} \] and \( f^* \) Generalized external force vector and generalized control force vector
\[ C^* \] Generalized damping matrix
\[ g \] Principal coordinates
\[ u(t) \] Control input
\[ r(t) \] External input to the system
\[ y(t) \] Output of the system, i.e., sensor output
\[ x(t) \] State vector
\[ A, B, C, D \] State space matrices (CT) : System, input, output, transmission matrix
\[ E \] External load matrix, which couples the disturbance to the system
\[ \dot{x}(t) \] Derivative of the state vector
\[ \mathfrak{N}^n \] \( n \) dimension space
\[ \tau \] Sampling interval in seconds
\[ C_0, D_0 \] Lifted system matrices
\[ \Phi, \Gamma \] System matrix, input matrix discretized at sampling interval of \( \tau \) secs
\[ \Phi, \Gamma \] System matrix, input matrix discretized at sampling interval of \( \Delta \) secs
\[ G \] Output injection gain
\[ U \] Controllability index of the system
\[ u_k, y_k \] Input and output at the \( k^{th} \) instant
\[ K \] POF gain matrix
\[ \rho_1, \rho_2 \] Spectral norms
\[ I \] Identity matrix
