RBF Based Face Recognition and Expression Analysis

Praseeda Lekshmi.V

Dr.M.Sasikumar

Abstract—Facial recognition and expression analysis is rapidly becoming an area of intense interest in computer science and human-computer interaction design communities. The most expressive way humans display emotions is through facial expressions. In this paper skin and non-skin pixels were separated. Face regions were extracted from the detected skin regions. Facial expressions are analyzed from facial images by applying Gabor wavelet transform (GWT) and Discrete Cosine Transform (DCT) on face images. Radial Basis Function (RBF) Network is used to identify the person and to classify the facial expressions. Our method reliably works even with faces, which carry heavy expressions.

Keywords— Face Recognition, Radial Basis Function, Gabor Wavelet Transform, Discrete Cosine Transform

I. INTRODUCTION

FACE recognition is one of the most challenging research areas in the field of computer vision. Even though face exhibits different facial features, which can be instantly recognized by human eyes, it is very difficult for a computer to extract and use the information content from these features. Facial expression is the most powerful, natural, and immediate means for human beings to communicate their emotions and intentions. The face can express emotion sooner than people verbalize or even realize their feelings. The need for reliable recognition and identification of facial expression of users is obvious. Face identification and recognition has lead to the development of different algorithms for various applications such as automated access control, surveillance, image retrieval etc. Generally pattern recognition problem rely upon the features inherent in the pattern for efficient solution. The challenges associated with face detection and recognition problem are pose, occlusion, expression, varying lighting conditions etc. Facial expression analysis has wide range of applications in areas such as Human Computer Interaction (HCI), Psychological area, Image understanding, Face animation etc. Humans interact with each other both verbally and non-verbally. Conversations are usually dominated by facial expressions. But there are several problems in analyzing communication between human beings through non-verbal communication such as facial expressions by a computer because expressions are not always universal. Human face consists of main sensory inputs and sensory outputs. It is used to identify gender, ethnicity, attractiveness, personality, information about age etc. Further facial expressions can be ambiguous. They have several possible interpretations. To analyze the facial expression, face regions have to be detected first. Next step is to extract and represent the facial changes caused by facial expressions.

In this paper, we have addressed the Gabor wavelet transform, DCT and RBF method for face recognition and expression analysis from the detected face. Non-uniform down sampling is done. Our method yields a good performance ratio for both face identification and expression analysis.

Rest of the paper is organized as follows. Section 2 gives back ground and related works. Section 3, 4, and 5 deals with basics of Gabor Wavesets, Discrete Cosine Transforms. Section 6 discusses the proposed method. Results are given in section 7. Conclusions and future works are given in section 8.

II. BACKGROUND AND RELATED WORK

Most face recognition methods fall into two categories: Feature based and Holistic [4]. In feature-based method, face recognition relies on localization and detection of facial features such as eyes, nose, mouth and their geometrical relationships [6]. In holistic approach, entire facial image is encoded into a point on high dimensional space. Images are represented as Eigen images. Euclidian distance or mean square error of vectors is used for matching. A method based on Eigen faces is given in [8]. PCA [2] and Active Appearance Model (AAM) for recognizing faces are based on holistic approaches. In another approach, fast and accurate face detection is performed by skin color learning by neural network and segmentation technique [5]. In [1] face images are represented by 2-D wavelet subband coefficients and recognized by classification method based on kernel associative memory model. ICA [11] is performed on face images under two different conditions: In one condition, image is treated as a random variable and pixels are treated as outcomes and in the second condition which treated pixels as random variables and image as outcome. Facial expressions are extracted from the detailed analysis of eye region images is given in [3]. In the appearance based approaches given in [7].
facial images are recognized by warping of face images. Warping is obtained by automatic AAM processing.

Another method of classification of facial expression using Linear discriminant analysis (LDA) is explained in [10] in which the gabor features extracted using gabor filter banks are compressed by two stage PCA method. Kernel Eigen Space method based on class features for expression analysis is explained in [9].

III. GABOR WAVELETS

The main characteristics of wavelet are the possibility to provide a multiresolution analysis of the image in the form of coefficient matrices. Strong arguments for the use of multiresolution decomposition can be found in psycho visual research, which offers evidences that the human visual system processes the image in a multi scale way. Wavelets provide a time and frequency decomposition at the same time. Computational complexity of wavelets is linear with the number of computed coefficients. Thus the complexity is less compared to other fast transformations.

The Gabor wavelet representation of images allows description of spatial frequency structure in the image while preserving information about spatial relations. The response image of Gabor filter can be written as a correlation of input image I(x) with Gabor kernel P(x)

\[ a \phi(x_0) = \int I(x) P_\phi(x - x_0) \, dx \quad (1) \]

\[ p_k(x) = \frac{k^2}{\sigma^2} \exp \left( -\frac{k^2}{2\sigma^2} x^2 \right) \left( \exp \left( -\sigma^2 \frac{x^2}{2} \right) \right) \quad (2) \]

where \( k \) is the characteristic vector.

\[ k = (k_x, k_y) = (k_v \cos \theta_w, k_v \sin \theta_w) \]

\[ k_v = 2^{-\frac{v+2}{2}} \pi \quad ; \quad \theta_w = \frac{w \pi}{8} \]

Here v is the discrete set of different frequencies and w is the orientation.

IV. DISCRETE COSINE TRANSFORM

Discrete Cosine Transform of an \( N \times N \) cosine transform matrix \( C = [c_{k,n}] \) is defined as

\[ C(k,n) = I / \sqrt{N} \quad k = 0, n = 0...N-1 \]

\[ = \sqrt{2/N} \cos \left( \Pi (2n+1) k / 2N, k = 1...N-1 \right) \]

\[ N = 0...N-1 \]

The cosine transform is orthogonal, that is

\[ C = C^* \Rightarrow C^{-1} = C^T \quad (4) \]

The basis vectors of the cosine transform are the eigenvectors of the symmetric tri diagonal matrix as shown in Table.1.

On applying the DCT, the input signal will get decomposed into a set of basis images. For highly correlated data, cosine transforms show excellent energy compaction. Most of the energy will be represented by a few transform coefficients.

V. RADIAL BASIS FUNCTION

Radial functions are a special class of function. Their characteristic feature is that their response decreases (or increases) monotonically with distance from a central point. The centre, the distance scale, and the precise shape of the radial function are parameters of the model, all fixed if it is linear. A typical radial function is the Gaussian which, in the case of a scalar input, is

\[ h(x) = \exp(-x-x^2/\sigma^2) \quad (5) \]

Its parameters are its centre \( c \) and its radius.

No learning is involved in RBF networks. For pattern classification problems, the numbers of input nodes are equal to the number of elements in the feature vector and the numbers of output nodes are equal to the number of different clusters. A radial basis function network is shown in Fig.1
VI. PROPOSED APPROACH

The first step in face detection problem is to extract facial areas from the background. The input images contain regions other than face such as hair, hat etc. Hence it is required to identify the face. Each pixel in the image is classified as skin pixel or non-skin pixel. Different skin regions are detected from the image. Face regions are identified from the detected skin region. The detected faces are shown in figure 2.

Here, each image is convolved with a Gabor kernel of variance and bandwidth as $\pi$ and a window size of $7 \times 7$. Five orientations are also used. Gabor filter outputs eleven sub images for each image with size $140 \times 140 \times 11$. The Gabor filter outputs are shown in Fig 4. DCT is also applied to images. The wavelet coefficients and DCT coefficients are computed and used for a RBF based neural network.

VII. RESULTS

In this approach skin and non-skin pixels were separated. Face regions were extracted from the detected skin regions. The expressions within the face regions were analysed. The expressions used were 'happy', 'normal', 'surprise', and 'anger'. Face images were normalized to a uniform size of $140 \times 140$. Gabor wavelet
filtering was done on the face images so that 11 sub images were produced for each normalized image. The Gabor coefficients and DCT coefficients are given to a neural network to classify the expression. The test image was also subjected to wavelet transform and DCT followed by neural network to identify the face and expression belongs to it.

The efficiency plots for three sets of images are shown in Fig. 5 (a) and (b). From the figure, it is shown that there is a slight decrease in the performance of recognizing the expression ‘Happy’ compared to others. This is because there are no considerable variations in the geometry of mouth region for neutral face and happy face. The expression ‘Anger’ has better performance of nearly 100%. The performance ratios for surprise and neutral are almost same.

Fig. 5. Efficiency plot

VII. CONCLUSION

In this paper, face recognition and expression classification from face images are explained. Skin and non-skin pixels are separated. Face regions are extracted from the detected skin regions. The expressions with in the face regions are analyzed. Input images are normalized to a uniform size. A holistic based approach in which whole face is considered for the analysis. Images are grouped based on expressions. Gabor filtering and Cosine transformations are done on face images and the resulting vectors are used for neural network. The test image is also subjected to preprocessing steps and the coefficients are given to a probabilistic based neural network. Thus person identification and expression classification is performed.

We have proposed a method to improve the efficiency and to increase the database by including more complex expressions as a future work. It is also proposed to extend the work to identify the face and it’s expressions from 3D images.
