An Iterative Method for Quaternionic Linear Equations

Bin Yu, Minghui Wang, Juntao Zhang

Abstract—By the real representation of the quaternionic matrix, an iterative method for quaternionic linear equations $Ax = b$ is proposed. Then the convergence conditions are obtained. At last, a numerical example is given to illustrate the efficiency of this method.

Keywords—Quaternionic linear equations, Real representation, Iterative algorithm.

I. INTRODUCTION

In quaternionic quantum mechanics and some other applications of quaternions[1], [2], [3], the problem of solutions of quaternionic linear equations is often encountered. Because of noncommutativity of quaternions, solving quaternionic linear equations is difficult. In papers[4], [5], [6], [7], by means of a complex representation and a companion vector, the authors have studied quaternionic linear equations and presented a Cramer rule for quaternionic linear equations and an algebraic algorithm for the least squares problem, respectively, in quaternionic quantum theory. In the paper[8], by using the complex representation of quaternionic matrices, and the Moore-Penrose generalized inverse, the authors derive the expressions of the least squares solution with the least norm, the least squares pure imaginary solution with the least norm, and the least squares real solution with the least norm for the quaternion matrix equation $AX = B$, respectively.

In the paper [9] and [10], by means of a real representation of the quaternionic matrix, we gave an iterative algorithms for the least squares problem in quaternionic quantum theory, and the relation between the positive (semi)definite solutions of quaternionic matrix equations and those of corresponding real matrix equations, respectively.

In this paper, we will pay attention to quaternionic linear equations $Ax = b$ by means of the real representation, and propose an iterative method, which is more suitable in the large-scale systems.

Let $R$ denote the real number field, $\mathbb{Q} = R \oplus Ri \oplus Rj \oplus Rk$ the quaternion field, where

$$i^2 = j^2 = k^2 = -1, ij = -ji = k.$$

Let $A_l \in \mathbb{R}^{m \times n}(l = 1, 2, 3, 4)$. The real representation matrix is defined[7] in the form

$$A^R = \left( \begin{array}{ccc} A_1 & -A_2 & -A_3 & -A_4 \\ A_2 & A_1 & -A_4 & A_3 \\ A_3 & A_4 & A_1 & -A_2 \\ -A_4 & A_3 & -A_2 & A_1 \end{array} \right) \in \mathbb{R}^{4n \times 4n}. \hspace{1cm} (1)$$

The real matrix $A^R$ is uniquely determined by quaternion matrix

$$A = A_1 + A_2i + A_3j + A_4k \in Q^{m \times n},$$

and it is said to be a real representation matrix of quaternion matrix $A$.

Then it is easy to verify the following properties.

Proposition 1.[10] Let $A, B \in Q^{m \times n}, C \in Q^{n \times s}, \alpha \in \mathbb{R}$. Then

$$(A + B)^R = A^R + B^R, (\alpha A)^R = \alpha A^R, (AC)^R = A^R C^R.$$ 

II. MAIN RESULTS

In this section, we will give an iterative method for

$$Ax = b,$$ 

that is,

$$\begin{pmatrix} A_1 & -A_2 & -A_3 & -A_4 \\ A_2 & A_1 & -A_4 & A_3 \\ A_3 & A_4 & A_1 & -A_2 \\ -A_4 & A_3 & -A_2 & A_1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} b_1 \\ -b_2 \\ -b_3 \\ -b_4 \end{pmatrix},$$

which may be written as

$$\begin{pmatrix} A_1 \\ A_2 \\ A_3 \\ A_4 \end{pmatrix} \begin{pmatrix} A_1 \\ A_4 \\ -A_3 \\ 0 \end{pmatrix} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \begin{pmatrix} -x_2 \\ -x_3 \\ x_4 \\ -x_1 \end{pmatrix}$$

or

$$\begin{pmatrix} 0 & -A_2 & -A_3 & -A_4 \\ -A_2 & 0 & -A_4 & A_3 \\ A_3 & A_4 & 0 & -A_2 \\ A_4 & -A_3 & A_2 & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \end{pmatrix}.$$
It follows from Proposition 1 that the above formula is equivalent to
\[
\begin{align*}
A_1 x_1 &= A_2 x_2 + A_3 x_3 + A_4 x_4 + b_1 \\
A_1 x_2 &= -A_2 x_1 + A_3 x_3 - A_4 x_4 + b_2 \\
A_1 x_3 &= -A_3 x_1 - A_4 x_2 + A_4 x_3 + b_3 \\
A_1 x_4 &= -A_4 x_1 + A_4 x_3 + A_4 x_4 + b_4 
\end{align*}
\]
So we can construct the iterative algorithm as follows:

Algorithm 1. the algorithm for \( Ax = b \)

(I). Initialization. Given arbitrary \( x_1^{(0)}, x_2^{(0)}, x_3^{(0)}, x_4^{(0)} \);

(II). Iteration. For \( l = 1, 2, \cdots \)
\[
\begin{align*}
x_1^{(l+1)} &= A_1^{-1} (A_2 x_2^{(l)} + A_3 x_3^{(l)} + A_4 x_4^{(l)} + b_1) \\
x_2^{(l+1)} &= -A_1^{-1} (A_2 x_1^{(l)} + A_3 x_3^{(l)} - A_4 x_4^{(l)} + b_2) \\
x_3^{(l+1)} &= -A_1^{-1} (A_3 x_1^{(l)} - A_4 x_2^{(l)} + A_4 x_3^{(l)} + b_3) \\
x_4^{(l+1)} &= -A_1^{-1} (A_4 x_1^{(l)} + A_3 x_2^{(l)} - A_3 x_3^{(l)} + b_4) 
\end{align*}
\]

(III). check convergence.

Theorem 2. If \( \| A_1^{-1} (A_l) \| < 1, l = 2, 3, 4 \), then the sequence \( \{ x_1^{(l)}, x_2^{(l)}, x_3^{(l)}, x_4^{(l)} \} \), generated by Algorithm 1, converges to \( x = x_1^{(\ast)} + x_2^{(\ast)} i + x_3^{(\ast)} j + x_4^{(\ast)} k \)

is the solution of (2).

Proof. we can easily obtain
\[
x_1^{(l+1)} - x_1^{(\ast)} = A_1^{-1} (A_2 x_2^{(l)} - x_2^{(\ast)} + A_3 (x_3^{(l)} - x_3^{(\ast)}) + A_4 (x_4^{(l)} - x_4^{(\ast)}))
\]
\[
= \sum_{i=1}^{l} f_i (A_1^{-1} A_2, A_1^{-1} A_3, A_1^{-1} A_4) (x_i^{(l)} - x_i^{(\ast)})
\]
where \( f_i (x,y,z) \) is a \( (l + 1) \)-order homogeneous polynomial on \( x, y, z \).

If \( \| A_1^{-1} (A_l) \| < 1, l = 2, 3, 4 \), it is obvious that
\[x_1^{(l)} \rightarrow x_1^{(\ast)}.
\]

Similarly, \( x_i^{(l)} \rightarrow x_i^{(\ast)}, i = 2, 3, 4 \)

Since the iterative matrix of Algorithm 1 is
\[
B = \begin{pmatrix}
0 & -A_1^{-1} A_2 & -A_1^{-1} A_3 & -A_1^{-1} A_4 \\
A_1^{-1} A_2 & 0 & -A_1^{-1} A_4 & A_1^{-1} A_3 \\
A_1^{-1} A_3 & A_1^{-1} A_4 & 0 & -A_1^{-1} A_2 \\
A_1^{-1} A_4 & -A_1^{-1} A_3 & A_1^{-1} A_2 & 0
\end{pmatrix},
\]
we can get the following result.

Theorem 3. If and only if \( \rho (B) < 1 \), the sequence \( \{ x_1^{(l)}, x_2^{(l)}, x_3^{(l)}, x_4^{(l)} \} \), generated by Algorithm 1, converges to \( x = x_1^{(\ast)} + x_2^{(\ast)} i + x_3^{(\ast)} j + x_4^{(\ast)} k \)

is the solution of (2).

III. NUMERICAL EXAMPLE

In this section, we present a numerical example to illustrate the efficiency of our algorithm.

Given \( A = A_1 + A_2 i + A_3 j + A_4 k, x = x_1 + x_2 i + x_3 j + x_4 k \)

with
\[
A \equiv \begin{pmatrix}
9 & 12 & -37 & 6 \\
-8 & 0 & 19 & -7 \\
17 & 43 & -19 & 0 \\
78 & -98 & 0 & 12
\end{pmatrix},
\]
\[
x = (1 + 4 - 4, x_2 = (0 - 7 8 11), x_3 = (-8 14 - 20 3), x_4 = (32 14 0 - 17))
\]
\[A = b_1 + b_2 i + b_3 j + b_4 k \equiv Ax.
\]

\( A \) and \( A_1 \) are nonsingular, \( Ax = b \) has a unique solution \( x \).

Fig. 1. The error of the computed solutions by Algorithm 1

Fig. 1 depicts the relation of the \( k \)-step approximate
\[
x^{(l)} = x_1^{(l)} + x_2^{(l)} i + x_3^{(l)} j + x_4^{(l)} k
\]

and the true solution \( x \). From Fig. 1, we can see that Algorithm 1 is efficient for this example.
