Computational Initial Value Method for Vibration Analysis of Symmetrically Laminated Composite Plate

Ahmed M. Farag, Wael F. Mohamed, Atef A. Ata, and Burhamy M. Burhamy

Abstract—In the present paper, an improved initial value numerical technique is presented to analyze the free vibration of symmetrically laminated rectangular plate. A combination of the initial value method (IV) and the finite differences (FD) devices is utilized to develop the present (IVFD) technique. The achieved technique is applied to the equation of motion of vibrating laminated rectangular plate under various types of boundary conditions. Three common types of laminated symmetrically cross-ply, orthotropic and isotropic plates are analyzed here. The convergence and accuracy of the presented Initial Value-Finite Differences (IVFD) technique have been examined. Also, the merits and validity of improved technique are satisfied via comparing the obtained results with those available in literature indicating good agreements.

Keywords—Free Vibrations, Initial Value, Finite Differences, Laminated plates.

I. INTRODUCTION

LAMINATED plates are often used in many engineering applications such as aerospace, naval and ocean structures. The great importance of the plate free vibration is due to the necessity of their dynamic characteristics. A proper optimization of the geometry of plate cross-section has to be carried out in order to achieve the required structural performance. For such plates, the governing partial differential equations of motion are solved either by numerical techniques, or experimentally to find the fundamental frequency of vibrations. Nowadays, many researches are devoted to the numerical analysis of the free vibration of plates. However, many problems remain still unsolved exactly. Due to its simplicity, the classical laminated plate theory (CLPT) [1] is widely used for the analysis of laminated plates which are subjected to dynamic loading. More complex plate theories have also been used, such as the first-order shear deformation theory (FSDT) and the third-order laminated theory[1]-[2]-[3]. It is very difficult to obtain the exact solution for the dynamic response of laminated composite plate. Currently, the exact solution can only be available for certain plate theories applied to simply support rectangular plates [3]. The main problems involving rectangular plates is classified into three distinct categories: (a) plates with all edges simply supported; (b) plates with a pair of opposite edges simply supported; (c) plates which do not classified on one of the above categories. The first and second categories are amenable to straightforward rigorous solutions in terms of the well-known Navier and Levy solutions [1]-[4]. These methods can be simply extended to orthotropic plates. Problems of the third category are difficult to be solved exactly [3]-[5]. Accordingly, rigorous analytical solutions, which satisfy the governing partial differential equations of motion and the boundary conditions exactly, turn out to be rare. Numerical methods have to be used if the problem involves complex geometries and complex boundary conditions. As a result, approximate numerical methods, [4]-[5]-[6], have been proposed for dynamic analysis of the laminated plates. Rayleigh-Ritz method is used in [7]-[8]-[9] to deal with the vibration problem of isotropic and orthotropic plates. More over Rayleigh-Ritz method[10]-[11]-[12] is employed with the method of superposition of normal modes to calculate the dynamic response of laminated plates with different boundary conditions. Many numerical methods have been proposed for the dynamic response analysis of plates. Out of these methods, the Finite Differences method (FD),[13]-[14]-[15], has become the universally applicable technique for solving boundary and initial value problems. Although Finite Element method (FE) [16]-[17], is an extremely versatile and powerful technique, it has certain disadvantages because large quantities of input data make implementation tedious, and one is often compelled to employ automatic mesh and load generation schemes. Also, many lower order elements will not yield acceptable stress results, necessitating the use of stress averaging or interpolation. So a computer core requirement can often be extremely large. Thus, there have been efforts to formulate alternative methods, which lead to the development of the Finite Strip method [2], Transition Matrix method [18], Initial Value method [19]-[20] and boundary element method [21]-[22].

The boundary element method [23]-[24]-[25] has been successfully applied for a great variety of problems, though a major deficiency. It is difficult to apply this method for anisotropic and inhomogeneous solids, as there is no simple applicable Green’s function available.
The main objective of the present paper is to offer a new numerical solution for free vibration analysis of symmetrically laminated plates. The capabilities of (IV) and (FD) methods are employed to achieve an improved (IVFD) hybrid numerical technique with reference to the solution for the title problem. Partial differential equation of vibrating plate is transformed at any node by the devices of the finite differences with respect to the neighboring nods in y-direction. A selected step by step initial integration method is applied in x-direction to solve the transformed differential equation. Some derivatives at the next nodal line are expressed according to trapezoidal rule.

The frequency parameters for such plates are obtained for different laminated composites, fiber orientation angles and boundary conditions. The results are compared with those available in the literature to examine the accuracy and efficiency of the method.

II. LAMINATED PLATE THEORY

Consider the rectangular plate whose dimensions in x and y directions are \( a \) and \( b \) respectively, as shown in Fig. 1. A number \( k \) of layers of fiber reinforced laminated composite lying in the \( x-y \) plane is applied to consist the overall thickness \( h \) of plate.

The reference plane \( z = 0 \) is located at the un-deformed mid-plane of the plate [26]-[27]. The \( z \)-axis is taken as positive upward from the mid-plane. The \( k^{th} \) layer is located between the two planes \( z = z_k - 1 \) and \( z = z_k \). The material principal axes 1 and 2 are oriented at an angle \( \alpha_k \) with respect to plate axis \( x \), as shown in Fig. 2. The magnitudes \( u, v \) and \( w \) denote the displacements in the coordinate directions \( x, y \) and \( z \) respectively. The displacements \( u \) and \( v \) can be expressed by \( w \) according to Classic Laminated Plate Theory CLPT [28]-[29]-[30] as follows:

\[
\begin{align*}
    u &= -z\dot{w}_x, \\
v &= -2\dot{w}_y
\end{align*}
\]  

(1)

where the suffix \( x \) or \( y \) refers to the partial derivative of \( \dot{w} \) with respect to \( x \) or \( y \) respectively.

![Fig. 1 The coordinate system of the composite laminated plate](image)

The strain-displacement relations [31]-[32]-[33] for the plate can be written in the matrix form such as:

\[
\begin{bmatrix}
    \varepsilon_x \\
    \varepsilon_y \\
    \gamma_{xy}
\end{bmatrix} = -zLw
\]  

(2)

where the differential operator \( L \) is given by:

\[
L^T = \begin{bmatrix}
\frac{\partial^2}{\partial x^2} & \frac{\partial^2}{\partial x \partial y} & \frac{\partial^2}{\partial x \partial z} \\
\frac{\partial^2}{\partial y \partial x} & \frac{\partial^2}{\partial y^2} & \frac{\partial^2}{\partial y \partial z} \\
\frac{\partial^2}{\partial z \partial x} & \frac{\partial^2}{\partial z \partial y} & \frac{\partial^2}{\partial z^2}
\end{bmatrix}
\]

The symbol \( ^T \) denotes transpose and \( \varepsilon_x, \varepsilon_y \) and \( \gamma_{xy} \) are the plate strains.

According to generalized Hooke’s law, the stress-strain relation for the \( k^{th} \) layer in the laminate coordinates is given by:

\[
\begin{bmatrix}
    \sigma_x \\
    \sigma_y \\
    \tau_{xy}
\end{bmatrix}^k = \begin{bmatrix}
    D_{11} & D_{12} & D_{13} \\
    D_{21} & D_{22} & D_{23} \\
    D_{31} & D_{32} & D_{33}
\end{bmatrix}^k \begin{bmatrix}
    \varepsilon_x \\
    \varepsilon_y \\
    \gamma_{xy}
\end{bmatrix}
\]  

(3)

or it is simplified to be in form:
\[
\begin{pmatrix}
\sigma_x \\
\sigma_y \\
\tau_{xy}
\end{pmatrix}
= Q
\begin{pmatrix}
\varepsilon_x \\
\varepsilon_y \\
\gamma_{xy}
\end{pmatrix}
\]  

(4)

where:

\[ Q^k = \frac{1}{\sqrt{T^k T^T}} = \begin{bmatrix} m & ml & ml \\ m^2 & m^2 & ml^2 \\ 2ml & ml & -ml^2 \end{bmatrix} \]

in which \( Q^k \) is the matrix of material constants for the \( k \)th layer in the material principal coordinates, whose elements are:

\[
Q_{11} = \frac{E_1}{(1 - \nu_{12} \nu_{23})}, \quad Q_{12} = \frac{\nu_{12} E_2}{(1 - \nu_{12} \nu_{23})},
\]

\[
Q_{22} = \frac{E_2}{(1 - \nu_{12} \nu_{23})}, \quad Q_{46} = G_{12}, \quad Q_{16} = Q_{26} = 0
\]

(5)

where \( E_1 \) and \( E_2 \) are Young’s moduli in the directions parallel and perpendicular to the fibers, respectively; \( G_{12} \) is the shear modulus and \( \nu_{12} \) and \( \nu_{23} \) are Poisson’s ratios.

The case of symmetrically stacked laminates is considered. And the bending moment vector is defined as:

\[
\begin{bmatrix}
M_x \\
M_y \\
M_{xy}
\end{bmatrix} = -D L w
\]

(6)

where, the matrix \( D \) is the coefficient matrix of the bending stiffness, which is given as:

\[
D = \begin{bmatrix}
D_{11} & D_{12} & D_{16} \\
D_{12} & D_{22} & D_{26} \\
D_{16} & D_{26} & D_{66}
\end{bmatrix}
\]

(7)

Such that,

\[
D_{ij} = \frac{1}{3} \sum_k (\overline{Q})_{ij} \left( z^i_k - z^j_{k+1} \right)
\]

(8)

and the shear forces are expressed as:

\[
q_x = \frac{\partial M_x}{\partial x} + \frac{\partial M_y}{\partial y}, \quad q_y = \frac{\partial M_x}{\partial y} - \frac{\partial M_y}{\partial x}
\]

(9)

III. INITIAL VALUE FINITE DIFFERENCES MATHEMATICAL FORMULATION OF LAMINATED PLATE

The lateral mid-plane deflection of the laminated plate is assumed to satisfy the following governing partial differential equation of motion for free vibration [1]-[34]-[35] as:

\[
D_{11} \dddot{w}_{xxxx} + 4D_{16} \dddot{w}_{xxyy} + 2(D_{12} + 2D_{66}) \dddot{w}_{xyxy} + 4D_{26} \dddot{w}_{yyyy} + D_{22} \dddot{w}_{yyyy} + I_0 \dddot{w}_x + I_2 \dddot{w}_y = 0
\]

(10)

where:

\[
I_0 = \sum_k (\rho) (z^2_k - z^2_{k+1})
\]

(11)

in which \((\rho)\) is the \( k \)th mass per unit volume.

The magnitudes \( \dddot{w}_{xxxx} \) and \( \dddot{w}_{yyyy} \) are the fourth-order partial derivatives of \( \dddot{w} \) with respect to \( x \) and \( y \) respectively. By analogy, the other partial derivatives of \( \dddot{w} \) are written according to the independent variables. To investigate the vibration modes, the displacement is defined as time harmonic function in the form:

\[
w(x, y, t) = \hat{w}(x, y) e^{i \omega t}
\]

(12)

where \( \omega \) is the circular natural frequency.

Substitution of (11) into (10) yields:

\[
D_{11} \dddot{w}_{xxxx} + 4D_{16} \dddot{w}_{xxyy} + 2(D_{12} + 2D_{66}) \dddot{w}_{xyxy} + 4D_{26} \dddot{w}_{yyyy} + I_0 \dddot{w}_x + I_2 \dddot{w}_y = 0
\]

The model of \( NM \times NH \) mesh of plate with equal divisions, \( \frac{H}{a} \) in \( x \)-direction and \( \frac{b}{M} \) in \( y \)-direction, is constructed, as shown in Fig. 3.

In the present paper a step by step integration technique is used by Initial Value method in the \( x \)-direction. So the partial derivatives \( \dddot{w}_{xxyy}, \dddot{w}_{xxxx} \) at any point \((i, j)\) in (10), are represented in \( y \)-direction by the lower displacement derivatives \( \dddot{w} \) and \( \dddot{q}_{xy} \) of four neighborhood points [36]-[37]-
[38], while the derivatives \( \frac{\partial^n \hat{w}}{\partial x^n} \); \( n=1,2,3,4 \) in \( x \)-direction are remained. Rearranging, the equation of motion (12) at point \((i,j)\) one can get:

\[
\hat{w}_{xxyy} = - \frac{4D_{10}}{D_{11}} \hat{w}_{xxyy} - \frac{2(D_{12} + 2D_{16})}{D_{11}} \hat{w}_{xxyy} - \frac{2D_{26}}{D_{11}} \hat{w}_{xxyy} - \frac{D_{22}}{D_{11}} \hat{w}_{xxyy} + \frac{\sigma_x^2}{D_{11}} \left[ w_0 x - I_2 \left[ \hat{w}_{xxyy} + \hat{w}_{xxyy} \right] \right] \tag{13}
\]

According to the basics of the Finite Differences [39]-[40], one can obtain:

\[
\left( \hat{w}_{xxyy}(i,j) \right) = \frac{1}{2G^2} \left[ \left( \hat{w}_{xxyy}(i,j+1) - 2(\hat{w}_{xxyy}(i,j)) + \hat{w}_{xxyy}(i,j-1) \right) \right] \tag{14}
\]

\[
\left( \hat{w}_{xxyy}(i,j) \right) = \frac{1}{G^2} \left[ \left( \hat{w}_{xxyy}(i,j+1) - 2(\hat{w}_{xxyy}(i,j)) + \hat{w}_{xxyy}(i,j-1) \right) \right] \tag{15}
\]

\[
\left( \hat{w}_{xxyy}(i,j) \right) = \frac{1}{2G} \left[ \left( \hat{w}_{xxyy}(i,j+1) - 2(\hat{w}_{xxyy}(i,j)) + \hat{w}_{xxyy}(i,j-1) \right) \right] \tag{16}
\]

\[
\left( \hat{w}_{xxyy}(i,j) \right) = \frac{1}{G} \left[ \left( \hat{w}_{xxyy}(i,j+1) - 4(\hat{w}_{xxyy}(i,j)) + 6\hat{w}_{xxyy}(i,j) \right) \right] \tag{17}
\]

Substitution from (14) to (17) into (13), the nodal equation of motion of laminated plates is reduced to:

\[
\left( \hat{w}_{xxyy}(i,j) \right) = \beta_1 \left[ \left( \hat{w}_{xxyy}(i,j+1) - 2(\hat{w}_{xxyy}(i,j)) + \hat{w}_{xxyy}(i,j-1) \right) \right] \\
+ \beta_2 \left[ \left( \hat{w}_{xxyy}(i,j+1) - 2(\hat{w}_{xxyy}(i,j)) + \hat{w}_{xxyy}(i,j-1) \right) \right] \\
+ \beta_3 \left[ \left( \hat{w}_{xxyy}(i,j+1) - 2(\hat{w}_{xxyy}(i,j)) + \hat{w}_{xxyy}(i,j-1) \right) \right] \\
+ \beta_4 \left[ \left( \hat{w}_{xxyy}(i,j+1) - 4(\hat{w}_{xxyy}(i,j)) + 6\hat{w}_{xxyy}(i,j) \right) \right] \\
+ \beta_5 \left[ I_0 x - I_2 \left( \hat{w}_{xxyy}(i,j) \right) \right] \tag{18}
\]

where:

\[
\beta_1 = - \frac{4D_{10}}{D_{11}} \frac{1}{2G^2}, \quad \beta_2 = - \frac{2(D_{12} + 2D_{16})}{D_{11}} \frac{1}{G^2}, \\
\beta_3 = \frac{4D_{26}}{D_{11}} \frac{1}{2G^2}, \quad \beta_4 = - \frac{2D_{22}}{D_{11}} \frac{1}{G^2}, \quad \beta_5 = \frac{\sigma_x^2}{D_{11}}
\]

The selected integration method used for solving the reduced differential equation in \( x \)-direction is the trapezoidal method, where some derivatives applied at a point \((i,j)\) are expressed as:

\[
\hat{w}^{(n)}(i,j) = \hat{w}^{(n)}(i-1,j) + \frac{H}{2} \left[ \hat{w}^{(n+1)}(i-1,j) + \hat{w}^{(n+1)}(i,j) \right] ; n=0,1,2,3,4 \tag{19}
\]

where \( \hat{w}^{(n)}(i,j) \) is the \( n \)-order derivative of the displacement \( \hat{w}(i,j) \) at a point \((i,j)\) with respect to \( x \).

The procedure of the step by step integration is explained in the following steps:

**Step1:** Assuming initial values at starting line \( i = 1 \)

Along edge \( i = 1 \), two quantities of the deflections and their derivatives \( \hat{w}^{(n)}(i,j) ; n=1,2,3,4,5,6 \) are known from the boundary conditions at this edge where other values are assumed. For example, let the boundaries at all plate edges are being simply supported. So at \( i = 1 \) because the deflection and moment at point \((i,j)\) are equal zero, then \( \hat{w}(i,j) = 0 \), \( \hat{w}_{xxyy}(i,j) = 0 \) for all \( j = 1,2,3,\ldots,M \). At the same edge \( i = 1 \), the other values \( \hat{w}^{(n)}(i,j) \) and \( \hat{w}_{xxyy}(i,j) \) for all \( j = 1,2,3,\ldots,M \) must be assumed in an alternative way as shown in table 1. Then by applying (18) at line \( i = 1 \) and \( j = 1,2,3,\ldots,M \) the corresponding values of the fourth derivative \( \hat{w}_{xxyy}(i,j) \) are obtained. Hence all values at line \( i = 1 \) are known.

**Step2:** Estimating derivatives values for the subsequent line

Generally, if all values at the line \( i \) are determined, one can transmit to line \((i+1)\). So, at the line \( i = 2 \), the partial derivatives \( \hat{w}_{xxyy}(i,j) \) for all \( j \) are assumed to take the same values of the previous line \( i = 1 \) for each corresponding point \( j \). Accordingly, deflection \( \hat{w} \) and the partial derivatives \( \hat{w}^{(n)}(i,j) ; n=1,2,3,\ldots,M \) at line \( i = 2 \) are calculated from trapezoidal rule , (19), from the known values of the

Note: the assumed initial values \( \hat{w}^{(0)}(1,j) \) are nonzero values.
corresponding values at the previous line \( i = 1 \). Consequently, by substituting the obtained quantities from trapezoidal rule into (18), the values of the fourth derivative \( (\dddot{w}_{ss})_{i,j} \) for all \( js \) can be determined.

**Step3:** Calculating the correct values by iteration technique

If the determined values of the fourth derivative \( (\dddot{w}_{ss})_{i,j} \), from (18), are not coincide with the assumed ones, then the new determined value is taken as the assumed value. So the procedure of step 2 has to be repeated for all possible \( j = 1,2,3,\ldots,M \), until the assumed value agrees as closely as with the deduced one for all \( js \).

**Step4:** Integrating the entire mesh of plate

Steps 2 and 3 are applied to the next lines \( i = 3,4,5,\ldots,N \). Since the previous steps were applied to line \( i = N \), then the deflection \( \dddot{w} \) and their partial derivatives, \( \frac{\partial^{4} \dddot{w}}{\partial x^{4}} ; n = 1,2,3,4 \), were found at the points of the terminal edge.

**Step5:** Superposition of homogenous solutions

Of course, as there are assumed initial values at the beginning edge \( i = 1 \), so the terminal boundary conditions are not satisfied. Hence it is a necessary to apply \( 2M \) -homogeneous solutions, each homogenous solution is corresponding to each assumed initial value at single point \( (i,j) \). The integration procedure explained previously is applied for each solution across the structure until the terminal edge \( i = N \) is reached. So there will be \( 2M \) sets of displacement quantities at each point \( (i,j) \) of the mesh (corresponding to each of the \( 2M \) - assumed initial values). The superposition method can be used to deal with individual solutions.

**Step6:** Satisfying the boundary condition at the end edge \( i = N \)

Because the individual solutions of the end edge \( i = N \) will not be satisfied with boundary condition, it is necessary to force the superimposed solutions to coincide with the boundary conditions. For example, the deflection and its second partial derivative must be zero for simply supported boundary conditions. For example, when the deflection and its second partial derivative must be zero for simply supported boundary conditions. For example, when the deflection and its second partial derivative must be zero for simply supported boundary conditions.

The true solution of any displacement quantities or one of its derivatives is the sum of the \( 2M \) - homogeneous solutions:

\[
\dddot{w}^{(s)} = \sum_{j=1}^{2M} b_j \dddot{w}_{s}^{(j)} ; n = 0,1,2,3,4 , s = 1,2,3,\ldots,2M \quad (21)
\]

where:

\( \dddot{w}^{(s)} \) is the true \( n \)-order partial derivative of the displacement of the superimposed solutions, for simply support terminal edge, \( \dddot{w}^{(0)} = \dddot{w} = 0 \) , \( \dddot{w}^{(2)} = \dddot{w}_{ss} = 0 \).

\( \dddot{w}_{s}^{(j)} \) is the \( n \)-derivative of the displacement of the homogenous solutions.

The unknown factors \( b_j ; s = 1,2,3,\ldots,2M \) are determined by satisfying the boundary conditions of the terminal edge \( i = N \). Equation (21) will be expressed in a matrix form, such as:

\[
\left[ R_i \right] \left[ b_s \right] = \left[ 0 \right] ; s = 1,2,3,\ldots,2M \quad (22)
\]

Where \( R_i \) is \( 2M \times 2M \) known matrix and \( b_s \) is \( 2M \) unknown vector.

**Step7:** Calculating the circular natural frequency of plate

For a non-trivial solution of (22), the determinate of \( [R_i] \) must be zero.

All values that satisfies zero determinate of \( [R_i] \) are the natural frequencies \( \omega \) of plate. The corresponding displacement of obtained natural frequency is the mode shape [41]-[42]-[43]:

\[
\left( \dddot{w}_{s}^{(j)} \right) = \sum_{s=1}^{2M} b_j \left( \dddot{w}_{s}^{(j)} \right) ; s = 1,2,3,\ldots,2M \quad (23)
\]

**IV. DIFFERENT TYPES OF BOUNDARY CONDITIONS**

Dealing with the boundary conditions, at edges of the rectangular plate, plays an important rule when applying the IVFD method. The assumed initial values at the edge \( i = 1 \) are depending on the boundary conditions along this edge.

The following table shows the different types of boundary conditions and the assigned initial values at first edge for all \( js \) for different boundary conditions [19].

<table>

\]

International Scholarly and Scientific Research & Innovation 7(1) 2013 64 scholar.waset.org/1307-6892/5143
The boundary conditions along the two edges \( j = 1 \) and \( j = M \) are expressed by finite differences basics to represent the displacement at the outer virtual points of these edges as shown in Table II.

### V. PARTICULAR TYPES OF PLATES

#### A. Orthotropic Plate

The one layer orthotropic material is characterized by the fact that the mechanical elastic properties have two perpendicular planes of symmetry\[44]-\[45]. Consequently, elastic constants are defined as:

\[
D_{11} = \frac{E_1 h^3}{12(1 - \nu_{12}\nu_{21})}, \quad D_{22} = \frac{E_2 h^3}{12(1 - \nu_{12}\nu_{21})},
\]

\[
D_{66} = \frac{G_{12} h^3}{12}, \quad D_{12} = \nu_{12} D_{22} = \nu_{21} D_{11}
\]  

(24)

Using the Kirchhoff hypotheses, the governing differential equation of motion for free vibration of the orthotropic plate can be represented as follows \[46]-\[47]:

\[
\ddot{w}_{xxxx} + \frac{2(D_{12} + 2D_{66})}{D_{11}} \ddot{w}_{xxyy} + \frac{D_{12}}{D_{11}} \ddot{w}_{yyy} - \lambda^2 \ddot{w} = 0
\]

(25)

where: \( \lambda^2 = \frac{\rho h a^2}{D} \) is the natural frequency parameter.

#### B. Isotropic Plate:

The isotropic plate is expressed from orthotropic plate, when \( D_{11} = D_{22} = 2(D_{12} + 2D_{66}) = D \). So the partial differential equation of motion of plate takes the form \[48]:

\[
\ddot{w}_{xxxx} + 2 \ddot{w}_{xxyy} + \ddot{w}_{yyy} - \lambda^2 \ddot{w} = 0
\]

(26)

where: \( \lambda^2 = \frac{\rho h a^2}{D} \), \( D = \frac{E h^3}{12(1 - \nu^2)} \) in which \( E \) and \( \nu \) are the modulus of elasticity and Poisson's ratio respectively.

### VI. NUMERICAL VERIFICATION AND DISCUSSION

#### Case 1: Laminated Cross-ply Symmetrical Plate

In this case, the treated problems are related to a four-ply and a three-ply composite plates with fully simply supported edges SSSS. Each layer is of a high-modulus graphite-epoxy material. The properties of this material are shown in the following table:

<table>
<thead>
<tr>
<th>Material</th>
<th>( E_1/E_2 )</th>
<th>( G_{12} )</th>
<th>( \nu_{12} )</th>
<th>( \rho/\text{t/m} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>M1</td>
<td>20</td>
<td>0.5E_2</td>
<td>0.25</td>
<td>1.54</td>
</tr>
</tbody>
</table>

The normalized dimensionless natural frequency parameter \( \Omega \) is defined as follows:

\[
\Omega = \sqrt{\frac{a^2}{\pi^2} \frac{\rho h}{D_{22}}}
\]

The results of \( \Omega \) for the treated problem are compared with the exact solution [1] showing a well convergence as shown in table IV. This convergence is due to exceeding of mesh nodal lines. As seen from results, the error decreases and be stable when the number \( N \) of the nodal lines in direction of initial value method be greater than the number \( M \) of nodal lines in the other direction.

The dimensionless natural frequency parameter \( \Omega \) deduced from the new method is illustrated in table V. The results are obtained for \( N = 12, M = 42 \) and compared with the exact values showing good agreements. Also, the natural frequency parameters are obtained for the variation of aspect ratio from 0.5 to 3.0 as shown in table VI.

Another case for different orthotropic ratios is studied for fully simply supported square plate with material M1. The normalized dimensionless natural frequency parameters are compared with those obtained by Nallim [50] and Khdeir [49] as shown in Tables VII and VIII. The results show a good agreement for the lower mode of vibration.

The mode shape is drawn for different modes of the studied plate of material M1 as shown in graphs from Fig. 4-a to Fig. 4-h in the appendix.

### Case 2: Orthotropic Plate

Orthotropic plates with two different types of materials, shown in Table IX, are investigated for the cases of fully clamped square plate CCCC. Another case of simple-simple-clamped-clamped SSCC is studied. The results are listed in table X for material M2 and in Table XI for material M3. The natural frequency parameters $\lambda$ are calculated for the first three modes of vibration and compared with those obtained Exacted and with Finite Element Method (FEM) [41].

### Case 3: Isotropic Plate

A square Isotropic plate is considered with $E = 2.0 \times 10^7$ t/m$^2$ and $\nu = 0.3$. The natural frequency dimensionless parameter $\lambda = \frac{a^2}{t \nu E}$ is determined for different cases of boundary conditions in the following tables:

The results are calculated for different modes of vibrations yielding a good accuracy in comparison with those of other literature.

VII. CONCLUSION

The developed Initial Value-Finite Differences method IVFD is successfully applied for free vibration analysis of symmetrically laminated plates with different combinations of boundary conditions. Results show that the natural frequencies calculated using the IVFD method agreed closely with the results in the published literature. The solutions converge rapidly for small number of nodal lines of finite differences direction when the number of nodal lines of initial value direction increases. However, it is noticed that the number of the nodal lines in the direction of the initial value method have to be greater than the number of the nodal lines chosen for the other direction of finite difference method. This difference is due to the iteration involved in the initial value technique. In addition, the method has been easily used in the analysis of different materials types of such plates as laminated, orthotropic and isotropic. The method can be extended to in the future work to investigate the dynamic problems of different shapes of such plates as, circular plate or stepped plate or plates with hollow.

APPENDIX

Different Modes of vibration for laminated cross-ply plate cited in Table III.
