Fuel Cell/DC-DC Convertor Control by Sliding Mode Method

Farzad Abdous

Abstract—Fuel cell's system requires regulating circuit for voltage and current in order to control power in case of connecting to other generative devices or load. In this paper Fuel cell system and convertor, which is a multi-variable system, are controlled using sliding mode method. Use of weighting matrix in design procedure made it possible to regulate speed of control. Simulation results show the robustness and accuracy of proposed controller for controlling desired of outputs.

Keywords—DC-DC converter, Fuel cell, PEM, Slides mode control.

I. INTRODUCTION

HUMAN'S life nowadays depends on electrical energy more than ever, thus the importance of generating energy increases significantly. Because of economical and ecological problems of fossil fuel power plants, developing renewable energies for generating electrical power attracts many attentions. Fuel cells are alternative power sources that have recently attracted a great deal of attention. Fuel Cell generates electricity from hydrogen by a chemical process and their emissions are water. Fuel Cell can serve as an emergency source of energy in the event of a long-term power outage. Fuel cell could be used as portable power systems. The fuel cells are finding use in every aspect because of their clean and efficient way of supplying electric power. The fuel cells are used in the standalone purposes at homes, hospitals, industries and now are finding their use in numerous vehicles. The fuel cells are replacing the batteries and in the current trend are becoming the most widely used resources.

Between different kinds of Fuel Cell, Proton Exchange Membrane (PEM) is the most famous one. In PEM electrochemical power is generated by passing gas of Hydrogen from anode and Oxygen from cathode. There is an electrolyte between Anode and Cathode which fasten the electric charge (Fig.1) [1].

Voltage of each cell in normal condition is 1.2 volt. For supporting high power and voltage couple of cells must be connected in series. Use of this system as a support of energy needs power control. Because of this a DC/DC convertor is usually connected between fuel cell and load. DC/DC convertors are used in applications which an average output voltage is needed; this voltage can be more or less than input voltage.

Several switching strategies are introduced to gain such voltage [2-6].

Proposed models for fuel cell usually neglect the effect of DC/DC convertor. [7] Introduces state space model of DMFC, while [8] discusses such model for SOFC. In [1] state space model and transfer function are discussed for the combination of PEM fuel cell and related DC/DC convertor. Introduced model is a multivariable one with two input and output. In this model there exist two different control signals, one is continues and other is binary related to switching.

In nonlinear models it is possible to use different control methods such as: Feedback Linearization, Fuzzy Control, Robust Control and Sliding mode control [9-12]. In this paper sliding mode is chosen as control method.

This paper is organized as follows. Section II introduces proposed system and its model. Sliding mode controller is designed in section III. And finally, simulation results and conclusions are in sections IV and V respectively.

II. SYSTEM MODEL

A valid model for Fuel Cell and DC/DC convertor is introduced in [1]. Circuit of this model is illustrated in Fig.2.
Appendix 1 explains elements and equations between parameters of Fig. 2.

In illustrated system, $i_l$, $v_c$, and $v_{CFC}$ are state variables. $E_{	ext{Nernst}}$ of Fuel Cell (controllable by pressure of $H_2$ and $O_2$) and switching signal $d$ of DC/DC convertor are assumed to be control signals. Output current of Fuel Cell ($i_L$) and output voltage of DC/DC convertor ($v_C$) are considered as outputs of system. Defined variables are as followed:

$$\dot{x} = [x_1 \, x_2 \, x_3]^T = [i_L \, v_C \, v_{CFC}]^T$$

$$u = [u_1 \, u_2]^T = [E_{	ext{Nernst}} \, d]^T$$

$$y = [y_1 \, y_2]^T = [i_L \, v_C]^T$$

For reaching state space equations of proposed system, switching signal $d$ considered to be 0 or 1.

In case of $d$ equal zero, shown in Fig. 3, state space equations are:

$$\begin{align*}
\dot{i}_L &= \frac{1}{L} (v_{CF} - v_c) \\
\dot{v}_C &= \frac{1}{C} (i_L - \frac{v_C}{r_C}) \\
\dot{v}_{CFC} &= \frac{1}{C} (i_L - \frac{v_C}{r_C})
\end{align*}$$

For $d$ equal one, illustrated in Fig. 4, it can be written:

$$\begin{align*}
\dot{i}_L &= \frac{1}{L} v_{CF} \\
\dot{v}_C &= \frac{1}{C} \left( \frac{v_C}{r_C} \right) \\
\dot{v}_{CFC} &= \frac{1}{C} \left( i_L - \frac{v_C}{r_C} \right)
\end{align*}$$

With control signal $u_2$, (4) and (5) can be written as:

$$\begin{align*}
\begin{cases}
\dot{i}_L &= \frac{1}{L} (v_{CF} - v_c + v_{CFC} u_2) \\
\dot{v}_C &= \frac{1}{C} \left( \frac{v_C}{r_C} + \frac{2 v_C}{r_C} u_2 \right) \\
\dot{v}_{CFC} &= \frac{1}{C} \left( i_L - \frac{v_C}{r_C} \right)
\end{cases}
\end{align*}$$

For converting (8) in standard form of (9), nonlinear functions $f(x)$ and $g(x)$ are defined as followed:

$$\begin{align*}
\dot{x} &= f(x) + g(x)u \\
&= \begin{bmatrix}
\frac{NR_{\text{Ohm}}}{L} & 0 & 0 \\
0 & -\frac{1}{C_{\text{C}}} & 1 \\
\frac{1}{C} & 0 & -\frac{1}{C_{\text{C}}}
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
x_3
\end{bmatrix}
\begin{bmatrix}
u_1 \\
u_2
\end{bmatrix}
\end{align*}$$

III. SLIDING MODE CONTROL

Objective control for proposed system is to deliver system outputs to desire values. Sliding mode method of control is used for this goal. In sliding mode method, control surfaces can be expressed as:

$$S_1 = x_1 - x_1^r$$

$$S_2 = x_2 - x_2^r$$

$$S = [S_1 \, S_2]^T$$

$$\dot{S} = S_1 + S_2 = 0$$

Fig. 4 circuit of system for $d=1$
\( x_{1p} \) and \( x_{2p} \) are desired values of desired values of state variables \( x_1 \) and \( x_2 \) respectively.

Lyapunov-like function is defined as follows:

\[
V = \frac{1}{2} S^T W S
\]

Based on (15) it can be written:

\[
\dot{V} = S^T W \dot{S}
\]

From (14), \( S' \) is:

\[
\dot{S} = [\dot{x}_1 \ \dot{x}_2]^T = f_1(x) + g_1(x)u
\]

(17)

\( f_1(x) \) and \( g_1(x) \) are sub matrices related to state variables \( x_1, x_2 \) from matrices \( f(x) \) and \( g(x) \).

With substituting (17) in (16) we deduced:

\[
\dot{V} = S^T W f_1(x) + S^T W g_1(x)u
\]

(18)

It is assumed that signal control \( u_e \) exists that can make control surface equal zero.

\[
S|_{u_e = 0} = 0
\]

(19)

From (18) and (19) it can be written:

\[
0 = S^T W f_1(x) + S^T W g_1(x)u_e
\]

(20)

Reducing (18) from (20) it can be written:

\[
\dot{V} = S^T W g_1(x)(u - u_e)
\]

(21)

Matrix \( g_1(x) \) is considered as:

\[
g_1(x) = [g_{11}(x) \ g_{12}(x)]
\]

(22)

From (21) and (22) it can be written:

\[
\dot{V} = S^T W g_{11}(x)(u_1 - u_{e1}) + S^T W g_{12}(x)(u_2 - u_{e2})
\]

(23)

\( u_{e1} \) and \( u_{e2} \) are signal control of \( u_1 \) and \( u_2 \), respectively. Signal controls \( u_1 \) and \( u_2 \) must be in the way that:

\[
\dot{V} < 0
\]

(24)

\[
S^T W g_{11}(x)(u_1 - u_{e1}) < 0
\]

(25)

\[
S^T W g_{12}(x)(u_2 - u_{e2}) < 0
\]

(26)

Considering conditions (25) and (26), \( u_1, u_2 \) can be expressed as:

\[
\begin{cases}
  u_1 < u_{e1} & S^T W g_{11}(x) > 0 \\
  u_1 > u_{e1} & S^T W g_{11}(x) < 0
\end{cases}
\]

(27)

Control signal \( u_1 \) depends on Fuel Cell's voltage, thus, is continuous signal. Based on (27) it can be written:

\[
u_1 = u_{e1} - K \text{sgn}(S^T W g_{11}(x))
\]

(29)

Where \( K \) is a positive number and usually chosen to be small. For avoiding chattering other functions like \text{sat} can be used instead of \text{sgn}, so it can be written:

\[
u_1 = u_{e1} - K \text{sat}(\frac{S^T W g_{11}(x)}{\varphi})
\]

(30)

\( \varphi \) defines margins of linear function \text{sat}.

\( u_{e1} \) can be concluded from (19):

\[
S|_{u_e = 0} \rightarrow \dot{S}|_{u_e = 0} = 0
\]

(31)

From (17) and (31) we deduced:

\[
f_1(x) + g_1(x)u_e = 0
\]

(32)

Thus \( u_e \) is:

\[
u_e = -\text{inv}[g_{11}(x) g_{11}(x)] g_{11}(x) f_1(x)
\]

(33)

\( u_1 \) is a control signal for the switch, as a result has a binary nature. Signal \( u_{e2} \) is between 0 and 1, thus from (28) it can be written:

\[
\begin{cases}
  u_2 = 0 & S^T W g_{12}(x) > 0 \\
  u_2 = 1 & S^T W g_{12}(x) < 0
\end{cases}
\]

(34)

Based on (31) \( u_2 \) is:

\[
u_2 = \frac{1}{2}[1 - \text{sgn}(S^T W g_{12}(x))]
\]

(35)

For simplification matrix \( W \) is usually chose to be diagonal as follows:

\[
W = \begin{bmatrix}
  a & 0 \\
  0 & b
\end{bmatrix}
\]

(36)

IV. SIMULATION

This section discusses operation of designed controller. For introduced model in section 2, parameters are as indicated in appendix 2. As a result \( f(x) \) and \( g(x) \) can be expressed as:

\[
f(x) = \begin{bmatrix}
  -499.14 & -13333 & 13333 \\
  0 & -1385.8 & 0 \\
  2.564.1 & 0 & -1385.8
\end{bmatrix}
\]

(37)
From state equation (37) sub matrices \( f_1(x) \) and \( g_1(x) \) can be written:

\[
f_1(x) = \begin{bmatrix} -499.14 & -13333 & 13333 \\ 0 & -1385.8 & 0 \end{bmatrix}
\]

\[
g_1(x) = \begin{bmatrix} 13333 & 13333 x_2 \\ 0 & 2771.5 x_2 \end{bmatrix}
\]

From (30), (35), (36), (40) we deduced:

\[
u_1 = u_{e1} - K s a t \left( \frac{13333 a (x_1 - x_{1e})}{\phi} \right)
\]

\[
u_2 = \frac{1}{2} [1 - \text{sgn}(13333 a x_2 [x_1 - x_{1e}] + 2771.5 b x_2 [x_2 - x_{2e}])]
\]

Parameters \( K, b, a \) and \( \phi \) are based on Table I:

<table>
<thead>
<tr>
<th>CONTROL PARAMETERS</th>
<th>VALUES</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a )</td>
<td>1</td>
</tr>
<tr>
<td>( b )</td>
<td>2</td>
</tr>
<tr>
<td>( \phi )</td>
<td>0.5</td>
</tr>
</tbody>
</table>

With assuming outputs \( i_1 \) and \( v_C \) to be 45.9 and 75.1 and must go to 46.99 and 75.35. Time response of system with designed controller is shown in Fig.5.

Effect of weighing parameters \( a, b \) on rate of response is noticeable. With choosing \( a, b \) as it indicated in Table II, time response in same conditions of previous case is as shown in Fig.6.

<table>
<thead>
<tr>
<th>CONTROL PARAMETERS</th>
<th>VALUES</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a )</td>
<td>0.5</td>
</tr>
<tr>
<td>( b )</td>
<td>2</td>
</tr>
</tbody>
</table>

It can be concluded that with changing weighing parameters, it is possible to achieve different control characteristics especially in time response speed. Based on this some other methods like genetic algorithm can be used too, however this option is not considered in this paper.

V. CONCLUSION

Controlling related systems is an important aspect of control. This paper is considering a system composed of a Fuel Cell and its DC/DC convertor as a unique system and discusses about its control methods. Designed controller is based on sliding mode method, which has the capability to control output voltage and current of Fuel Cell at any level. Considering weighing matrix made the procedure more flexible. Simulation results show the effectiveness and robustness of proposed method.
