A Thermodynamic Solution for the Static and Dynamic Characteristics of a Two-Lobe Journal Bearing

B. Chetti, W. A. Crosby

Abstract—The work described in this paper is an investigation of the static and dynamic characteristics of two-lobe journal bearings taking into consideration the thermal effects. A thermo-hydrodynamic solution of a finite two-lobe journal bearing is performed by solving the generalized form Reynolds equation with the energy equation, taking into consideration viscosity variation across the film thickness. The static and dynamic characteristics were numerically obtained. The results are evaluated for different values of viscosity-temperature coefficient and Peclet number. The results show that considering the thermal effects in the solution of the two-lobe journal bearing has a marked on the study of its stability.

Keywords—Two-lobe bearing, thermal effect, static and dynamic characteristics.

I. INTRODUCTION

The circular bearing is extensively used in engineering applications due to its manufacturing simplicity, but unfortunately it may suffer from instability problems at high rotational speeds. The instability produced by hydrodynamic forces in bearings is characterized by large amplitude vibration, which can result in bearing and therefore total machine failure. Non-circular bearings have the advantage of being more stable at higher speeds. Of the various non-circular journal bearings, the two-lobe journal bearing is considered quite attractive owing to its relative ease of manufacture.

The performance characteristics of two-lobe journal bearings have been studied by a number of investigators. Pinkus [1] and Kumar [2] theoretically investigated the effects of ellipticity on the static and dynamic characteristics, but they dealt with the laminar flow regime. This work was improved by introducing the turbulent flow regime [3]-[5]. On the other hand, Abdul-Wahed et al. [6] calculated the dynamic characteristics of 6 types of multi-lobe journal bearings in turbulent flow regime. Elasto-hydrodynamic effects were introduced in the study of two-lobe journal bearings by many researchers [7]-[9]. Tayal et al. [10] investigated the performance of two-lobe journal bearings lubricated with a non-Newtonian fluid. The foregoing analyses have been predominantly isothermal in approach.

Thermohydrodynamic solutions were first reported by Dowson and co-workers [11]. Numerous analyses of the thermo-hydrodynamic aspects in bearings followed [12]-[15].

II. PRESSURE EQUATION

If we neglect the variation in the lubricant's density, the generalized Reynolds equation could be written in the following normalized form:

\[
\frac{\partial}{\partial \theta} \left( \frac{H^3}{\eta} \frac{\partial p}{\partial \theta} \right) + B^2 \left( \frac{\partial}{\partial \eta} \left( \frac{H^3}{\eta} \frac{\partial p}{\partial \eta} \right) \right) = \frac{\partial}{\partial \theta} \left( H \left( \frac{1}{I_2} - \frac{1}{I_2} \right) \right) \frac{\partial H}{\partial \eta}
\]  

The non-dimensional film thickness \( H \) is given by, Fig. 1:

\[
H = 1 - \varepsilon \left( \cos \theta \sin \phi - \sin \theta \cos \phi \right) \pm \delta \sin \theta
\]

where

\[
\varepsilon = \varepsilon (1 - \delta) \quad \text{and} \quad P = p \left( \frac{\varepsilon}{R} \right)^2 / \mu_1 \omega
\]

The negative and positive signs in (2) are used to determine the film thickness in upper lobe and lower lobe respectively. And the integrals

\[
I_0 = \int_0^1 \eta d \eta ; \quad I_1 = \int_0^1 \eta \eta d \eta ; \quad I_2 = \int_0^1 \frac{\eta}{\mu} \left( \eta - \frac{I_1}{I_0} \right) d \eta
\]

This equation is then set into a finite difference form by using central difference scheme.

W.A. Crosby is with the Mechanical Department, Faculty of Engineering, University of Alexandria, Alexandria, Egypt.

Keywords—Two-lobe bearing, thermal effect, static and dynamic characteristics.
A. Pressure Boundary Conditions

The boundary conditions are:

\[ P(\theta, 0) = P(\theta, 1) = 0. \] (5)

\[ P(\theta_1, \zeta) = 0; \quad P(\theta_2, \zeta) = 0. \] (6)

\[ \frac{\partial P}{\partial \theta}(\theta_1, \zeta) = 0; \quad \frac{\partial P}{\partial \theta}(\theta_2, \zeta) = 0. \] (7)

and

\[ P(\theta, \zeta) = 0 \quad \text{for} \quad \theta_1 \geq \theta \geq \theta_1 \quad \text{and} \quad \theta_2 \geq \theta \geq \theta_2 \] (8)

III. TEMPERATURE EQUATION

The temperature distribution within the oil film is determined by the following form of non-dimensional energy equation [17]

\[ \frac{1}{Pe} \left( \frac{\partial^2 T}{\partial \eta^2} \right) - H^2 u \left( \frac{\partial T}{\partial \theta} \right) + \mu \left( \frac{\partial u}{\partial \eta} \right)^2 = 0 \] (9)

where

\[ u = -H^2 \left( \frac{\partial P}{\partial \theta} \right) \left[ \frac{1}{I_o} \left( \frac{1}{\mu} \right) d\eta - \frac{1}{\frac{\alpha}{\mu}} d\eta \right] + 1 - \frac{1}{I_o} \frac{1}{\mu} d\eta \] (10)

\[ \frac{\partial u}{\partial \eta} = \mu \left( H^2 \left( \eta - \frac{1}{I_o} \right) \left( \frac{\partial P}{\partial \theta} \right) - \frac{1}{I_o} \right) \] (11)

\[ Pe = \frac{\rho C_p \alpha C_T^2}{k} \] is Peclet number

The non-dimensional viscosity \( \mu \) is assumed to be defined by the relationship

\[ \mu = \exp(\alpha T) \] (12)

where \( \alpha \) is a viscosity-temperature coefficient.

Equation (9) is of parabolic type and the Crank-Nicolson method is used to obtain the finite difference scheme.

A. Temperature Boundary Conditions

The boundary conditions for temperature are;

\[ T(\theta_1, \eta) = T(\theta_2, \eta) = T_i \] (13)

\[ T(\theta, 0) = T_j. \] (14)

\[ T_j = T_i. \] (15)

\[ \frac{\partial T(\theta, 1)}{\partial \eta} = 0 \] (16)

IV. STATIC CHARACTERISTICS

The static characteristics of the bearing are obtained by solving the Reynolds equation (1) for static loading \((x = y = 0)\) and the energy equation (9).

The numerical procedure adopted for obtaining the pressure and temperature fields are as follows:

An initial value for attitude angle \( \phi \) is assumed in order to calculate the film thickness by (2). Initial values of pressure are assumed to be zero at all points, and a suitable initial temperature is assumed, so that the viscosity at the nodal points could be calculated. The generalized Reynolds equation (1) is solved using Gauss-Seidel method with over-relaxation. Negative pressures are set to zero to account for Swift-Stieber boundary conditions. The velocity \( u \) and its gradient edge \( \frac{\partial u}{\partial \eta} \) are then computed at every nodal point. The energy equation is solved; thus a new temperature distribution is obtained. Convergence is assumed when at each point the relative difference in pressure between successive iterations does not exceed 0.1%. The horizontal and vertical load components

\[ W_x = \frac{1}{2} \int_0^\pi \int_0^{\theta_d} \rho \sin \theta d\theta d\zeta \quad W_y = \frac{1}{2} \int_0^\pi \int_0^{\theta_d} \rho \cos \theta d\theta d\zeta \] (17)

are computed. The equilibrium position of the journal is achieved when \( W_x \) is zero. A satisfactory value for \( \phi \) is considered to be attained if \( |W_x/W_y| \leq 0.001 \). Otherwise, another value of \( \phi \) is assumed.

V. DYNAMIC CHARACTERISTICS

The total stiffness coefficients for a multi-lobe bearing are given by:

\[ \begin{pmatrix} K_{xx} & K_{xy} \\ K_{yx} & K_{yy} \end{pmatrix} = \begin{pmatrix} \partial / \partial x \\ \partial / \partial y \end{pmatrix} \begin{bmatrix} W_x & W_y \end{bmatrix} \] (18)
In these equations the partial derivatives of \( x \) and \( y \) are found by changing \( x \) or \( y \) by a small value about the static equilibrium position of the bearing.

The expressions for damping coefficients are given by:

\[
\begin{pmatrix}
C_{xx} & C_{xy} \\
C_{yx} & C_{yy}
\end{pmatrix} = \begin{pmatrix}
\frac{\partial}{\partial x} \chi & \frac{\partial}{\partial y} \chi \\
\frac{\partial}{\partial x} \psi & \frac{\partial}{\partial y} \psi
\end{pmatrix} \begin{bmatrix}
W_x \\
W_y
\end{bmatrix} \quad (19)
\]

The partial derivatives of \( x \) and \( y \) are obtained by giving a small value to \( x \) and \( y \) respectively corresponding to the equilibrium position of the bearing.

VI. STABILITY ANALYSIS

The linearized equations of the disturbed motion of the journal centre are

\[
M \cdot \ddot{x} + K_{xx} \cdot x + C_{xx} \cdot \dot{x} + K_{xy} \cdot \dot{y} + C_{xy} \cdot y = 0
\]

\[
M \cdot \ddot{y} + K_{yx} \cdot x + C_{yx} \cdot \dot{x} + K_{yy} \cdot \dot{y} + C_{yy} \cdot y = 0
\]

Equations (20) are used to study the stability of the bearing system. Harmonic solution of the type:

\[
x = x e^{j\lambda t}, \quad y = y e^{j\lambda t}
\]

Thus (20) can be written as:

\[
\begin{bmatrix}
K_{xx} - M v^2 + i\nu C_{xx} & K_{xy} + i\nu C_{xy} \\
K_{yx} + i\nu C_{yx} & K_{yy} - M v^2 + i\nu C_{yy}
\end{bmatrix} \begin{bmatrix}
x \\
y
\end{bmatrix} = 0
\]

For a nontrivial solution the determinant must vanish and equating the real and imaginary parts to zero gives:

\[
\gamma^2 = \frac{K_{xx} \cdot K_{yy} + K_{yx} \cdot \overline{K_{xy}} + K_{xy} \cdot \overline{K_{yx}} + C_{xx} \cdot C_{yy}}{C_{xx} + C_{yy}} \quad (23)
\]

\[
\gamma^2 = \frac{(K_{xx} - M \gamma^2)(K_{yy} - M \gamma^2) - K_{yx} \cdot K_{xy}}{C_{xx} \cdot C_{yy} - C_{xy} \cdot C_{yx}} \quad (24)
\]

where

\[
\overline{C_{xy}} = \frac{C_{xy}}{W}, \quad \overline{K_{xy}} = \frac{K_{xy}}{W}, \quad M = \frac{M e \omega^2}{W}, \quad \gamma = \frac{\nu}{\omega}
\]

From (23) and (24), the critical mass and the whirl ratio \( \gamma \) are calculated. \( \overline{M} \) is the critical mass parameter above which the bearing is unstable.

VII. RESULTS AND DISCUSSION

Computer solutions for a two-lobe journal bearing with two supply grooves; each one has an angle of 20 deg, have been evaluated for one aspect ratio \( B = 1 \), three values of Peclet number (5, 50, 200) and three values of viscosity-temperature coefficient (0.01, 0.1, 0.3). The ellipticity ratio used here is 0.5.

Fig. 2 shows the variation of the maximum oil temperature \( T_{\text{max}} \) with the eccentricity ratio for different values of the viscosity-temperature coefficient and Peclet number. The value of \( T_{\text{max}} \) decreases with the increase of the viscosity-temperature coefficient (Fig. 2 (a)). This is due to the decreases of the oil viscosity. \( T_{\text{max}} \) increases with the increase of Peclet number and the eccentricity ratio (Fig. 2 (b)). The Peclet number is related to the velocity of journal, so if the velocity of journal increases the Peclet number increases and as a result, the temperature increases.

Fig. 3 gives the variation of the attitude angle with the eccentricity ratio corresponding to different values of viscosity-temperature coefficient and Peclet number. The curves show that the attitude angle increases with increasing of both viscosity-temperature coefficient and Peclet number. The effect of these two parameters on the load carrying capacity of bearing is shown in Fig. 4, an increase of \( \alpha \) and \( \text{Pe} \) produces a decrease of the load carrying capacity.
The stability charts are shown in Fig. 5 for various values of viscosity-temperature coefficient and Peclet number. The lower and upper sides of each curve corresponding to stable and unstable regions respectively. The critical mass decreases as the viscosity-temperature coefficient and Peclet number increase and the reduction being greater at higher eccentricity ratios. Fig. 6 exhibits the variation of whirl ratio with eccentricity ratio for different values of viscosity-temperature coefficient and Peclet number. From the figures, it can be seen that the whirl ratio increases with an increase of both $\alpha$ and $Pe$. The effect of these two parameters on whirl ratio is significant at higher eccentricity ratio.

**VI. CONCLUSIONS**

On the basis of the results and discussions presented in the previous section, the following conclusions are drawn:

1. The maximum temperature decreases with increases of the viscosity-temperature coefficient and with the decrease of Peclet number.
2. The attitude angle increases with the increase of the viscosity-temperature coefficient and with the increase of Peclet number.
3. For a given bearing geometry and eccentricity ratio, both the load carrying capacity and the critical mass decrease as the viscosity-temperature coefficient and Peclet number increase.
4. The whirl ratio increases with the increases of the viscosity-temperature coefficient and with the increase of Peclet number.
5. Considering the thermal effects in the solution of the two-lobe journal bearing, the thermohydrodynamic solution decreases the stability region and increases the whirl ratio.

**NOMENCLATURE**

- $B$: Aspect ratio
- $c$: The radial clearance
- $C_p$: Specific heat of lubricant
- $C_{ij}$: Damping coefficients
- $\overline{C_{ij}}$: Dimensionless damping coefficients, $C_{ij}e\omega/W$
- $e$: Eccentricity
- $h$: Oil film thickness
- $H$: Dimensionless oil film thickness, $h/c$
- $I_0, I_1, I_2$: Integrals given by equation (4)
- $K_{ij}$: Stiffness coefficients
- $\overline{K_{ij}}$: Dimensionless stiffness coefficients, $K_{ij}e/W$
- $L$: Bearing length
\[ M \] Mass of journal

\[ M_c \] Critical mass of journal

\[ \overline{M_c} \] Dimensionless critical mass of journal, \( \overline{M_c} = \frac{M_c}{W} \)

\[ p \] Pressure

\[ P \] Dimensionless pressure, \( \frac{p}{\mu \omega} \)

\[ R \] Journal radius

\[ S \] Sommerfeld number, \( S = \frac{1}{2\pi W} \)

\[ T \] Non-dimensional temperature

\[ T_j \] Non-dimensional inlet oil temperature

\[ T_f \] Non-dimensional journal temperature

\[ u, v, w \] Velocity components

\[ U \] Velocity of the journal

\[ W \] Bearing load

\[ \overline{W} \] Dimensionless bearing load, \( \overline{W} = \frac{W}{\mu \omega RL} \)

\[ x, y, z \] Circumferential, radial and axial coordinates respectively

\[ \alpha \] Viscosity-temperature coefficient

\[ \delta \] Ellipticity ratio

\[ \varepsilon \] Eccentricity ratio, \( e / c \)

\[ \theta \] Angular coordinate

\[ \theta_{11}, \theta_{22} \] Angular coordinates at the end of the bearing

\[ \theta_{11'}, \theta_{22'} \] Angular coordinates at the start of the bearing

\[ \mu \] Lubricant Viscosity

\[ \rho \] Lubricant density

\[ \nu \] Whirl frequency

\[ \gamma \] Whirl ratio

\[ \phi \] Attitude angle

\[ \omega \] Angular velocity of the journal
